BINDING LIST JUN 15 1924

276-24

INDEX TO ENGINEERING NEWS-RECORD

VOLUME 91—July 1 to December 31, 1923

July 5.	1	to 41
July 12.	45	to 81
July 19.	85	to 124
July 26.	125	to 161
Aug. 2.	165	to 208
Aug. 9.	209	to 248
Aug. 16.	249	to 288
Aug. 23.	289	to 328
Aug. 30.	329	to 370
Sept. 6.	371	to 414
Sept. 13.	415	to 454
Sept. 20.	455	to 496
Sept. 27.	497	to 538
Oct. 4.	539	to 582
Oct. 11.	583	to 622
Oct. 18.	623	to 662
Oct. 25.	663	to 702
Nov. 1.	703	to 746
Nov. 8.	747	to 788
Nov. 15.	789	to 828
Nov. 22.	829	to 870
Nov. 29.	871	to 912
Dec. 6.	913	to 958
Dec. 13.	959	to 1000
Dec. 20.	1001	to 1048
Dec. 27.	1049	to 1080

A

Accelerators, effect on concrete.	a142
Accident prevention:	
Federal activities, safety provisions re-	
commended.	n650

ACCIDENTS

Brick wall collapses in wind storm, Brooklyn.	n33
Bureau of Standards, dynamometer laboratory explosion, four killed.	n57
Explosion caused by gasoline leak.	n615
Football stands. (See Grandstands.)	
Ice house, concrete, wrecked by overturning ice due to flood (C. W. Lusk).	*18

Aeronautics:

Deliberations in airplane maneuvering.	183
Building the Navy airship ZR1.	*e209, *212
Time for tribute, 20-year anniversary of first flight.	*e960

African railway:

Air vibrations due to fluttering of water sheet over dams (F. I. Winslow).	107
--	-----

Alaska:

Harding visit, "to open up Alaska."	*e85
Highway development by Alaska road commission (J. G. Steese).	*500

Alkali, effect on concrete, A.S.T.M. discussion:

Engineering trail making, revision and topographic and mining survey finished.	*995
--	------

Alaska-Lorraine reorganization by railways:

Aluminum paints reduce radiation.	*522
-----------------------------------	------

Aluminum Association of Engineers:

Dismissal of A. P. Davis from U. S. Reclamation Service, will ask Congress to investigate.	n156
--	------

American Association of Port Authorities:

acts on equipment design.	177
---------------------------	-----

American Association of State Highway Officials:

meeting.	*e991
----------	-------

American Automobile Association, broadcasting road information:

American Chemical Union, revision and water supply discussed at Milwaukee meeting.	n569
--	------

American Construction Council announces apprenticeship committee:

Meeting.	n487
----------	------

American Institute of Consulting Engineers:

Annual meeting.	n499, n589
-----------------	------------

Ethics Committee Case 21:

Calver, H. N. is sanitary engineer.	n403
-------------------------------------	------

American Public Health Association:

Convention contrasts.	*e623
-----------------------	-------

American Railway Bridge and Building Association:

Meeting.	n654
----------	------

American Society for Municipal Improvement:

City problems discussed at Atlanta (R. Townsfield, S. C. Rogers, L. A. S. Wood, H. P. Eddy, L. M. Fisher, C. D. Pollock).	*a850, n860
---	-------------

AMERICAN SOCIETY FOR TESTING MATERIALS

Annual meeting.	*e 22, a26
Concrete, behavior of, discussed at annual meeting.	*e46, 52
Endurance of concrete in tension, revision and impact tests, *e91, (D. J. McAdam).	*a298
Benefits of some researches in concrete, accelerators, tests to investigate durability tests, behavior of slabs aggregate.	*a142
Specifications and facts concerning materials.	22

AMERICAN SOCIETY OF CIVIL ENGINEERS

Building accidents and their prevention, report of committee on structural safety.	*e85, a88
Oment committee suggested.	*e583
Committee sees President Coolidge on federal reorganization.	n733
City Planning Division, organization.	n340
Davis, A. P., protest on removal of, from U. S. Reclamation Service.	n75, e85
Earthquake committee to investigate behavior of Japanese structures.	*e529, n571
Education for Promotion of Engineering Education, civil engineers appointed.	n1033
Grunsky, C. E., nominated as president.	n319

Meetings, Chicago, Ill.	102
Richmond, Va.	*e529, n993
Sanitary section, three in the field.	*e094
Society of Cooperated Engineers.	*e125
American Society of Mechanical Engineers.	
Low, Fred R., new president.	n014
Angle-bar weights, rule for computing.	*323
Angles, supporting brick veneer carried by inserts in concrete.	*n1037
Appointed rounds their (airship) progress.	*e329
Apprentices (See Labor, apprentices; Engineers, apprentices.)	
Arbitration Court, New York Building Congress.	*e829
Argentine-Chilean transline railway, building (R. F. Maury).	*332
Asphalt, simplification of grades, effective Jan. 1, 1924.	*n291, n658, 1093
Ash pits, water economy of (W. Volkhardt).	1520

ASSOCIATED GENERAL CONTRACTORS OF AMERICA

Ballots for Officers.	*n1031
Bargains, selection of.	*n31
Bidders' responsibilities studied by committee.	n616
Contractors' responsibility, A. G. C. to define.	*e583
Cranford, F. L., nominated as president.	*522
Denver chapter organized.	*n362
Economic conditions discussed.	*e59
Approved by committee.	n120
Citing opinion on need of 21-E.	n160
Tilting mixers discussed at conference.	n344
Augusta, Ga., unlikely to get channel to sea.	976
Austin reservoir (Texas). (See Reservoirs.)	
Australia, new North-South Ry.	n006
Austria, reorganizing railways of.	807

B

Backfilling to avoid settlement (L. B. Manheimer).	*113
Barge, upended, moved 43 miles by rail.	*522
Barges, selection of.	n006
Federal barge service, corporate management suggested.	n1033
Bayonet terminal rejects proposal for ship pier.	n528
Beaumont, Tex., rainfall of 12.76 in. in 48 hr.	63
Berkeley, Calif., freeways, concrete blocks.	n529
Bids. (See Contracting, bids.)	
Birmingham.	*116
Hunt, Robert W.	*e85, *116
Birdseye party, survey of Grand Canyon.	n043
Boas, (See Surveys, Colorado River.)	
Bonds.	
Issues voted on in November.	*n818
Municipal bond market overloaded.	*e623

BOOK REVIEWS

"Acoustics of Buildings" (F. R. Watson).	482
"Best-City Charter" (R. J. Hardinge).	813
"Brief Drawing" (R. C. Ringwalt).	648
"Bureau of Public Roads" (W. S. Holt).	275
"Business Cycle and Unemployment" (National Bureau of Economic Research).	275
"Capital and Steam Power" (J. Lord).	1027
"City Payments" (F. B. Brown).	109
"Civilization and Climate" (E. Huntington), reviewed by X. H. Goodnough.	1025
"Climate Changes and Their Causes" (E. Huntington), reviewed by X. H. Goodnough.	1025
"Domestic Sanitation and House Drainage" (British H. C. Adams).	484
"Doncaster" (England) Regional Planning Scheme (P. Abercrombie and T. H. Jefferies).	110
"Earth and Sun" (E. Huntington), reviewed by X. H. Goodnough.	1025
"Elasticity and Strength of Materials" (C. P. Turner), reviewed by George Paswell.	813
"English and the Engineer" (S. A. Harbarger).	648
"Estimating Building Costs" (C. F. Dingman).	483
"Everybody's Manager" (J. McCullough), an engineer's brief for a stable dollar.	109
"Fine Arts, Significance of," (American Institute of Architects).	273
"From Immigrant to Inventor" (Michael Pupin).	813
"Germany's Capacity to Pay" (H. G. Morgan).	484
"High-Pressure Reservoir Outlets," a Report on Bureau of Reclamation Installation" (J. M. Gaylord and J. L. Savage).	1026
"Hydraulic Principles Governing River and Harbor Construction" (C. M. Townsend).	273
"Hydraulics Applied to Sewer Design" (G. S. Coleman), reviewed by J. H. Gregory.	814
"Industrial Democracy" (G. E. Plumb and W. G. Roylance).	648
"Kut's Mechanical Engineers' Handbook" (R. T. Kent).	648
"Manual of Information on City Planning and Zoning" (T. Kimball).	483
"Motor Vehicle" (J. H. Amar), reviewed by G. C. Whipple.	273
"Motor Transportation of Merchandise and Passengers" (W. H. B. Collins).	814
"Office of Chief of Engineers" (W. S. Holt).	814
"Platform Speaking" (G. R. Collins), reviewed by F. E. McDonald.	812
"Prevention of Vibration and Noise" (A. B. Eason).	1027

"Railway Maintenance, Practical" (C. Weiss), reviewed by S. B. McConnell.	647
"Railways of Spain" (G. L. Bock).	*1027
"Relativity and Space, Four Lectures on" (C. P. Stenmetz), reviewed by G. G. Paswell.	644
"Seasoning and Other Concrete Ships" (N. K. Foster), reviewed by G. C. Hollister.	1025
"Site Planning in Practice" (F. L. Thompson).	274
"Text Book of Filtration, Industrial Filtration and the Various Types of Filters Used" (C. L. Bryden and G. D. Dickey), reviewed by R. S. Weston.	1026
"Town and Town Planning, Ancient and Modern" (T. H. Hughes).	274
"Trade Association Activities" (L. E. Warford, R. A. May, New York State "Ventilation," report of New York State Commission.	108
Boston, Mass., Metropolitan Planning Commission created.	15
Box-car ladder made from parts obtained from scrap pile.	*e888
Brakes:	
Solenoid brake, quick-acting for crane service.	*n202
Westinghouse brake for truck railroads.	806
Brazil road work organized.	n244

BRICK

Importation of brick and cement increasing.	*e620
Standard size for common brick adopted by manufacturers.	n200
Tests. (See U. S. Bureau of Standards.)	
Varieties reduced to two standard sizes.	n121

BRIDGE ABUTMENTS AND PIERS

Abutments, using a bridge to brace its abutment.	*350
Bronx River bridge abutment held by girder brackets (A. G. Hayden).	*112
Biscuits, Louisiana, pier construction.	795

BRIDGE ACCIDENTS

Highway bridge troubles.	*e839
Highway bridges, protecting from colliding vehicles (E. F. Kelley).	*e892
Morris Canal bridge, Jersey City, N. J., wrecked by overloaded truck.	*e014
Lynchburg, Cole Creek, Wyo., rains destroy trestle, wrecking Burlington train.	*n571
Stockton, N. Cal., bridge destroyed by bridge (C. A. Mead).	*e272
Tall unbraced timber posts cause falsework failure.	*16
Wapakoneta, Ohio, 40-year-old bridge destroyed by colliding automobile.	*n78
Bridge construction, Delaware River. (See Bridges, Philadelphia-Camden.)	

BRIDGE DESIGN

Bear Mountain bridge design attacked as ugly.	*e126, *156
Engineers for bridges.	*e251
Pittsburgh, Pa., truss bridges design (three Allegheny bridges) again under discussion.	n155
Dispute in bridge design.	n195
Strain-gage used to check bridge reinforcement.	19
Bridge engineers, tall unbraced timber posts, tall, unbraced, cause failure.	*16

BRIDGE FAILURES

Bascule bridges, demonstrated danger, failures at Sault Ste. Marie, Mich., and Montreal.	*e872
Cowit's County Wash., county liable.	*n800
Lachine Canal bridge, Canada, bascule counterweight falls drops bridge.	*n801
Morris Canal bridge, Jersey City, N. J., failure caused by collision.	*n778
Schenectady-Scott bridge falsework gives way, five killed.	*n487

BRIDGE FIRES

Cimarron River bridge, Guthrie, Okla.	n33
Fort Madison, Iowa, A. T. & S. F. Ry. bridge.	n33
Springfield, Mass., North End bridge, destroyed by fire.	n440, *n488, (See Bridges, Springfield.)
Stevens Point, Wis., six-span bridge destroyed by burning of timber floor.	n32
Bridge removal:	
Santa Fe Ry. moves six bridge spans 43 ft. endwise.	*152

BRIDGES

Approaches, capacity standards for motor traffic.	*e210
Arch:	
Watertown, N. Y., solve complicated river crossing with double-deck bridge (E. H. Harder).	*542
Bascule:	
Bending action in bascule bridge counterweight failures "Bridge Engineer".	1109
Lachine Canal, Canada, bascule counterweight falls.	*n801
Mystic, Conn., bascule bridge of new type and its construction (T. E. Brown).	*e374
And W. R. Brown.	*n801
Bear Mountain, design attacked as ugly.	*106
Belle Isle bridge opened.	*n905
Bronx Parkway bridges tested by heavy loads (A. G. Hayden).	*e934
Cantilever:	
Ohio, county highway, cantilever bridge, completed (F. M. Eason).	*191
Carnequin Strait bridge. (See Bridges, San Francisco Bay.)	

*Illustrated; a, abstracts; e, editorials; j, job and office; l, letter; n, news.

Chicago, Ill. lift-span bridge, Halsted St. requiring 925
 Chinese bridge, bids wanted 960
 Columbia River bridge tolls 722
Concrete
 Cantilever bridge of concrete, Ohio inter-county highway (P. M. Henry) 191
 France, two reinforced-concrete bridges, Yzeure River, near Nantes (W. L. Scott) 916
 Lackawanna R.R., two precast concrete bridges (M. Hirschthal) 381
 Maintenance, low, an asset, versus steel 6581
 Precast concrete units used for English footbridge 1004
 Sidney, Ohio, strength specifications for large concrete bridge 6580 (J. E. Huntley) 586
 Watertown, N. Y., solve complicated river crossing with double-deck bridge (E. H. Harder) 542
 Delaware River. (See Bridges, Philadelphia Camden.)
 Eyebarr-drain suspension bridge, Florianopolis, Brazil 592
 Girders. (See Girders.)
 Golden Gate. (See Bridges, San Francisco Bay.)
 High Bridge to be reconstructed, not destroyed 61, n30
Highway
 Railroad car sills and ties, bridge built (C. Tappan) 235
 Specification standards, three societies, art and craftsmanship 830
 Hudson River bridge, army engineers hear plan for 3363
 Hudson River, new bridge project for New York City 1072
 Kansas, low-water bridge built (C. O. Boynton) 1078
 Lake Worth, Fla., \$175,000 more asked 1450
 Low-water bridge built in Kansas (C. O. Boynton) 1080
 Ohio River at Louisville, municipal toll bridge, proposed 10034
 Palestine, bridge antedating Christian era still in service 177
 Philadelphia, South St. bridge opened 801
 Philadelphia, concrete bridge, \$450 460
 Cables, bids and contract, n372, n104, n362
 Steel erection, bids rejected 195
 Steelwork, bids rejected 195
 Pittsburgh, Pa., architects' design (three Allegheny bridges) again under discussion 135
 Dispute initiated by architects, n195
 Plaza plans, Jersey City, N. J., presented by aid of model 306
 Pontoon. (See Bridges, Springfield, Mass.)
 Portland, Ore., plans for two new bridges 522
 Railroad, concrete, expansion details (O. W. Gatchell) 520
 Ramps, concrete, on Montclair park bridge 377
 Railway, cast-iron bridge and trainshed on British railway replaced 365
 Raritan River bridge, Perth Amboy, N. J., bids rejected 573
 Rigolets bridge, Louisiana, built to withstand hurricanes; Louisiana, village R.R. 626
 Pier construction 795
 St. Paul, Minn., river bridge at new Ford plant 305
 San Francisco Bay
 Carquinez Strait bridge, first concrete piers poured 613
 Golden Gate, bridging 86
 Permits granted for two bridges 527
 Springfield, Mass., North End bridge destroyed by fire 449, n488
 New bridge authorized 734
 Pontoon bridge not suitable 821
 Red tape and pontoon bridge 6340
 Steel bridge to replace burned structure 861
 Steel maintenance 6584
 Suspension
 South America, Florianopolis, Brazil, large eyebarr-drain suspension bridge 592
 Temporary use on hydro-electric plant 523
 Gorham, N. H., bridge, reconstruction, flood protection measure in Seine River 673
 Vancouver, B. C., second Narrows bridge, contract let 241
 Wateree River, S. C., river and swamp crossing completed 281
 Wilmington, Del., concrete memorial bridge has attractive appearance 96
 Wooden bridge, old, heavy loads carried over (E. C. Gault) 441
 British. (See Great Britain.)
 Bucket loaders, tractor mounting for, n121
 Buffalo, N. Y., garbage pigery and residue drying chambers 458, 479

BUILDING DESIGN

Cut building cost and increase floor space by use of flats 343
 Rose Polytechnic Institute new, Terre Haute, Ind. 351
 Storage, Washington, Wash., building, has unusual design (S. T. Smith) 633
 Correction 727
 Truss supports for cantilevers of theater balconies 193

BUILDING FAILURES

Binghamton, N. Y., school building of brick and tile fails 528
 Building accidents and their prevention, report of Am. Soc. of E. committee 588
 Chicago, Union Station, headhouse, steel erection derrick falls 615
 No progress against bad building 690

BUILDING LAWS

Chicago, Ill., freight limits for buildings 837
 Floor load requirements, variations in 255
 Height restriction (A. H. C. Shaw) 1113
 Heights of buildings, limitation by law, 615
 Hoover committee on seasonal building organized 163
 Public buildings bill, Washington, D. C., before Administration 449
 Building heights (B. F. Affleck) 1277

BUILDING MOVING

Houses barged across Kanawha River, 369
 Los Angeles hotel moved to new site, n314
 Narrow-gauge tracks used in moving houses, new location, Hagerstown, Md. (E. G. McGill) 314
 Office building, 7,500-ton, Chicago, Ill., moved to provide for street extension 1771

BUILDINGS

Concrete
 Grauman's Theater in Los Angeles, huge concrete girders and trusses (I. R. C. Mitchell) 4
 Ice house wrecked by overturning ice due to flood (C. W. Lusk) 18
 Craftsman type architecture for industrial buildings 233
 Crystal Palace London, old cast-iron frame strengthened by steel framing 65
 Office buildings, space-saving office partitions 909
 Rochester, N. Y., compares three types of school buildings (A. R. Reilly) 880
 Theaters
 Knickerbocker theater, Washington, D. C., wins three damage suits, n945
 Los Angeles, Calif., Grauman's Theater, huge concrete girders and trusses (I. R. C. Mitchell) 4
 Bulb, electric, theft-proof 368
 Bureau of Standards. (See U. S. Bureau of Standards.)
 Business, Judge Gary, address on "What's ahead in business?" 736

C

Caissons, concrete
 Manchester ship canal to be closed against floating oil by concrete caisson (R. F. Mundorf) 171
 San Francisco Bay, China Basin, concrete caissons sunk in place for wharf and seawall (F. G. White) 252
 California, highways and public works 1116

CAMPS

Bunkhouse sterilizer uses live steam and cresosote oil. (See Contractors, war camp units.)
 San Joaquin River, Calif., construction camp built on canyon walls 317
 Sanitation of camp site in Wisconsin 377
 Sheets and pillow slips 6340
 Canadian Good Roads Association, meeting 14

CANALS

Concrete caisson to close Manchester ship canal against floating oil (R. F. Mundorf) 171
 Intercoastal, Corpus Christi, Tex., to unify commerce 96
 Intercoastal canals, Gen. Goethals to report on 239
 Manchester ship canal, England, concrete caisson to close canal against floating oil (R. F. Mundorf) 171
 New York Barge Canal
 Water diverted to be measured, n1033
 New York Canals Bureau. (See New York State.)
 Panama
 Fender chains protect Panama lock 153
 Gaillard cut, slide movement 1010
 Tonnage increases 366
 Water diverted to, and tolls, increase, no oil profits 372
 St. Lawrence ship canal, wanted by farmers 639
 Sault Ste. Marie, increasing traffic 466
 Sault Ste. Marie and Welland, show long-term increase 911
 Syracuse, N. Y., to fill bed of abandoned canals 176
 Car puller, electric, capstan, n37
 Car
 Gas car, new type, for narrow-gauge railway 326
 Keep cars for loaded and moving 447
 Self-contained steam railway coaches 17
 Cat-tails, elimination from reservoirs 502
 More about cat-tails (W. F. Lockhardt) 1612
 (See also Reservoirs.)

CEMENT

Alumina cement in France 6329, (E. C. Ebel) 477
 Cement Manufacturers Protective Association dissolved, n697, 6703, 726
 Committee on cement and American Society of Civil Engineers, suggested, n583
 Dealers' profits on cement to large users 67
 G. P. Reeves, cement supply, n1507, 1859
 Defense of cement supply, man (E. K. McCormack) 1692 (J. Brobston) 1730
 Foreign cement, "dumping" to be investigated 826
 Future requirements of cement, A.S.T.M. discussion (P. H. Bates) 452
 Impaction of brick and cement increasing 620
 Oil-well water, effect on cements 635
 Portland Cement Association investigator sent to Japan 658
 Prices, and 7.3 per cent income on investments of companies 671, n407, (See Cement, dealer's profits; and Cement, defense of supply man.)
 Selling cement by sack (L. T. Sunderland) 174
 Tests. (See U. S. Bureau of Standards.)
 Chamber of Commerce. (See U. S. Chamber of Commerce.)

CHICAGO, ILL.

Asphalt pavements, how examined (P. E. Green) 968
 Building height limits 52
 Calumet Harbor advocated for Chicago 15
 Chicago River, plans for straightening, n33
 Elevated extension, Evanston and Niles Cent. 903
 Grandstand at Chicago Ball Park, reconstruction 172
 Hydraulic gradient in water tunnels, determination of 606
 Illinois Central R.R. to start electrification 694
 Laying large cast-iron bridge, steel marking road routes through Chicago 457
 Office building, 7,500-ton, moved to provide for street extension 1771
 Railroad shophouse, order restraining in strikes made permanent 1115
 Rapid transit plan, express train, n326
 Regional planning, 30th Ward district, n1034
 Straus Bldg., seven plants fabricate steel for 794
 Transporting, 68-ton derrick, n523
 Terminal project, La Salle, Dearborn, Grand Central stations, consolidation, n861
 Transit, City Council plans union system 687, n104
 Union Station
 Building permit, \$6,000,000, granted, n188
 Forms double and terminal 1028
 Steel erection derrick at headhouse fails 615
 U. S. Senate committee, water disposal and waterway projects 819
 Water-waste prevention started 583
 Chicago Sanitary District
 Order entered against diversion of water, n33
 China, Relief Commission to construct utilities 903
 Clay, coolies and May-pole dance 990
 Cincinnati, Ohio, river terminal 862
 Cinder Concrete Association, National, formed 575

CITY MANAGERS

City Managers Association, Meeting, n906
 Cleveland, Ohio, W. R. Hopkins named city manager, n994
 Plainfield, N. J., city manager plan voted down 282
 Stockton, Calif., C. E. Asbburner City manager at \$20,000, n34

CITY PLANNING

Boston Metropolitan Planning Commission created 15
 Minnesota planning commission scheme started 1076
 New Orleans, La., planning and zoning commission appointed 242
 Zoning
 Milwaukee zoning ordinance upheld by state court 1073
 New Jersey cannot zone against two-family houses 281
 New Jersey, Butler zoning ordinance, part held unconstitutional 361
 New Orleans ordinance legal, says high state court 196
 Pittsburgh, Pa., Morris Knowles heads zoning appeals board 449
 St. Louis, Mo., suspension of zoning denied by court 946
 St. Louis zoning ordinance held invalid by state court 957
 Clamp safety for street cars 201
 Clay (china) handled by conveyors at British port 719
 Clay deposits, Pennsylvania, waste, burden disposal problem 444

COAL

Federal Coal Commission. (See Coal, U. S. Coal Commission.)
 Harding's death, its effect on coal situation, n239
 Moral suasion to cheapen coal, n499
 Pollution of water supplies by coal mine drainage, Pennsylvania, C. P. Collier 838
 Reserved coal lands, paying for, n29
 Stock piles control price 659
 Storage
 Detroit waterworks, storage building for year's supply of coal, n10
 F.A.S.E. active in pushing coal storage investigation 281
 Strikes. (See Labor, strikes, coal.)
 U. S. Coal Commission
 Duty in coal industry, n371
 Report on anthracite mines, n47, n75, 616
 Review of general recommendations, 98

Illustrated: a, abstracts; e, editorials; j, job and office; l, letter; n, news

- Urges supervision of industry by Interstate Commerce Commission.....n529
Who gets the dollars?.....n537
- Cofferdams**
Benton Harbor, Mich., crane excavates and builds cofferdam for filtered water basin.....n315
Coffin, C. A., gold medal awarded to General Electric Co.n733
- Cold storage**
Washington, D. C., cold storage warehouse has unusual design (S. T. Smith).....n633
Colombia, S. A., recent railway location (R. M. Miller).....n348
"Commerce Yearbook" (See U. S. Chamber of Commerce.)
- CONCRETE**
Alkali effect on concrete, A. S. T. M. discussion (G. M. Williams).....n356
American Concrete Institute meeting to emphasize progress in concrete.....n1041
American Society for Testing Materials, results of some researches in concrete.....n143
Atmosphere, effect on concrete, A. S. T. M. discussion (P. J. Freeman).....n54
Behavior of concrete, discussion at meeting of A. S. T. M.n46, n52
Bowers not active (J. C. Witty).....n523
Breaking up old concrete by hydraulic pressure (Ma. Johnstone-Taylor).....n443
Cinder concrete, discussion at meeting of A. S. T. M.n575
Cores, height measured by device (G. W. Hutchinson).....n690
Curing. (See Highway construction concrete.)
Filtered sprinkling water used to avoid iron stains, University of Illinois, stadium (G. C. Habermeyer).....n985
Mass concrete in service, A. S. T. M. discussion (J. C. Witty).....n523
Motorcycle track, concrete, in Prague.....n137
Piers:
Frost action in heaving concrete piers (L. D. McCready).....n360
Pipe elbow, concrete patch withstands heavy wear.....n148
Poles, concrete, for large Swedish transmission lines (F. A. Brackmann).....n136
Railway ties of concrete used in India.....n463
Seepage water, concrete, discussion at A. S. T. M. meeting (S. C. Hollister).....n55
Shed protects railway track from mud slides, Southern Pacific R.R., California.....n610
Slump tests, religion and drinking water (E. Godfrey).....n1730
Station platform, concrete, built for, 151
Swimming pool, Midland Beach, New York, inadequate design causes failure.....n383
Tank, concrete, leaks repaired in tank subjected to external water pressure (R. W. Horne).....n444
Tests, Core-drill tests of concrete roads, conclusions from (R. B. Gane).....n226
- CONCRETE AGGREGATE**
Blast furnace slag as an aggregate in concrete.....n446
Concrete aggregate produced from local deposits (J. A. Garrod).....n1012
New word for concrete aggregate (W. D. Browning).....n447

 Plainfield, N. J., test of acid in de-watering activated sludge. (J. R. Downs).....n129

Direct-oxidation

Austin, Minn., direct-oxidation process permitted.....n599, n993
 Minnesota, Ind., the list of approval.....n599
 New Jersey Hirsch-Potts charges are modified.....n157
 Trenton, N. J., direct-oxidation process again disapproved.....n198
 Trenton, N. J., rejection of plans by New Jersey State Board of Health "Promotion and ethics".....n210

Filtration:

Novel type of filter, stream-line. (G. W. Fuller).....n770
 Imhoff tanks:
 Alum shortens drying period of Imhoff tank sludge.....n888
 Methane gas from Imhoff tanks, utilization of. (Dr. Ing. K. Imhoff).....n512
 Newton, Kan., mechanical agitator in sum in vent chamber.....n301
 Plainfield, N. J., trial of acid in de-watering Imhoff tank sludge. (R. H. Eagles).....n1194

Trenton, N. J., (See Sewage treatment, direct oxidation)
 Worcester, Mass., City forces build Imhoff tanks and trickling filter. (E. R. Perry).....n832

SEWAGE WORKS

Gate-valve forced off pump main, Natick, Mass.....n591
 Indianapolis, Ind., (See Sewage treatment activated sludge)
 New York City, Wards Island disposal plant, preliminary steps.....n304
 Operation:
 Iowa sewage plant operators discuss.....n777
 Making sewage plant work.....n620
 Phillipsburg, N. J., defendants in conspiracy case acquitted.....n197
 Trenton, N. J., has to wait until Aug. 1, 1925, to build sewage-works.....n279
 Trenton, N. J., Hirsch-Potts hearing.....n115
 Worcester, Mass., city forces build new treatment works. (E. R. Perry).....n832
 Sewer Construction:
 Hammond, Ind.:
 Intercepting sewers and siphon built. (J. B. Murphy).....n58
 Twin tunnels for sewer siphon under Calumet River.....n50
 Sewer design:
 Tunnels, twin, and sewer siphon built under Calumet River at Hammond.....n50
 Sewer systems, and districts. (See sewerage.)
 Sewerage:
 Los Angeles County, new joint sewer district formed.....n778

SEWERS

East St. Louis enjoin sanitary sewer construction.....n30
 Intercepting, automatic, sewerage-flow later. (H. S. Phillips).....n442
 Manholes. (See Manholes.)
 Outlet for sewer through concrete dock. (D. H. Fleming).....n689
 Pascale Valley outfall sewer tunnel construction, rescinded.....n242
 Suspended structure carries sanitary sewer over stream. (J. C. Kelsey).....n148
 Shaft sinking:
 Rock shaft, New York City, taking care of water.....n691
 Shannessy, Lord, death of.....n993
 Siphon, in pillow shaft in tunnel.....n340
 Sherman law, sixteen companies fined for violations.....n782
 Shovels:
 Crane convertible to shovel.....n286
 Gasoline dipper shovel.....n326
 Revolving shovel, 4-yd., operates with only one motor.....n37
 Revolving steam shovel, 1 1/2-yd. heavy-duty.....n201
 Rope shackle, 10-yd. shovel.....n689
 Steam shovel moves steel storage tank.....n608
 Water pipe, heavy, placed by steam shovel.....n141
 Wood for own fuel broken up by steam shovel.....n586
 Sidney, Ohio, concrete bridge, strength specifications for. (J. B. Hunley).....n586
 Simplified Practice, division of Department of Commerce, to hold conference.....n453
 Sioux City, street widened by moving concrete curb and gutter sections. (J. D. Adams).....n611

Siphons:

Hammond, Ind.:
 Sewer siphons and twin tunnels built under Calumet River.....n59
 Siphons and intercepting sewer built. (J. B. Murphy).....n58
 Hetch Hetchy project, building a 9-ft. siphon on Hetch Hetchy aqueduct. (N. E. Bokart).....n100
 State producers investigate nailing problems.....n782

Slide

Fourth scale for log slide rule. (C. S. Jarvis).....n316
 Slump, (oil) religion, and.....n1730
 (See Concrete.)
 Smith, Grant, death of.....n571
 Smith, George, in appreciation. (M. J. Whitson).....n612
 Snow removal:
 National Park, steam shovel clears road.....n245
 Snow removal and road damages.....n550
 Twin rotary snow plow.....n988
 Snow plow, snow plow on tractor, clears full width of road.....n700

Society for Promotion of Engineering Education

Education committee of American Society of Civil Engineers, appointed.....n1033
 Soundings, simplifying taking of, under adverse conditions. (E. R. Pauntier).....n771
 South America:
 Florianopolis, Brazil, large eyebar-chain suspension bridge.....n592
 Spillways:
 Pit River Plant No. 1, California, surge tank and spillway.....n630

Stadium:

Count of football crowd, Ohio State University gives hints on stadium design. (E. Morris).....n985
 Grandstand at Chicago Ball Park, reconstruction.....n172
 Grandstands. See Grandstands.
 Indiana University, contract let.....n197
 Standardization conference, Zurich, Switzerland.....n321
 State engineering in the highway field.....n444

Steam power:

Gorkas plant sold to Alabama Power Co.....n531

Steel:

Designing steel details with attention to drainage. (A. M. Shaw).....n609
 Forms for concrete buildings, etc., service policy of Blaw Knox Co. A. C. Lehman.....n900
 Reinforcing steel, inspection from the outside, on contracts.....n498
 Roadbuilding, concrete, steel.....n410
 Steel forms successful on concrete job. Hupp Motor Co., Detroit. (H. C. Reese).....n392
 Steel industries plan exposition.....n286
 Straus Bldg. Chicago, seven plants fabricate steel for.....n794

Tests:

Endurance of steel in tension, torsion and impact, e201. (D. J. McAdams).....n298
 Illinois report, second, on endurance, e291. (H. F. Moore and T. M. Jaeger).....n308
 Welding. (See Welding.)
 Stennmetz, Dr. Charles P., death of.....n733
 Stone tests. (See U. S. Bureau of Standards.)
 Strain measuring:
 Optical-level extensometer of wide utility. (L. B. Tuckerman).....n206
 Strasburg Cathedral, modern engineering save tower.....n505
 Stream pollution:
 Philadelphia, conference of engineers on stream pollution.....n451
 Street cars, tramway standards, old, removed.....n525
 Street cleaning, motor cleaner has gutter-cleaning attachment.....n81

Street lighting:

Street lighting. A. S. M. E. discussion. (R. Teunfeldt, S. C. Rogers, L. A. S. Wood).....n850

Streets:

Canterbury, streets in days of Henry VIII and Elizabeth.....n132
 Sioux City, Iowa, street widened by moving concrete curb and gutter sections. (J. D. Adams).....n611
 Two-level street obviates costly grading. New York City. (H. W. Levy).....n853
 Structural details, by city engineers, practical and eccentric help joint. (C. Weiss).....n339; correction 383
 Structural details, American Society of Civil Engineers, New York, for section.....n695
 Stump puller, self-anchoring.....n536
 Subways:
 New York City, articles reprinted for reference.....n695
 Two new subways to be built.....n239
 London, accident on tube subway.....n1072

SURVEYS AND SURVEYING

Colorado River, Stanton's expedition of 1899. (P. S. Odell).....n1902
 Colorado River, survey by C. B. Birdseye and party.....n532, n571, n787, n808
 Level, hand, reflecting.....n454
 Measurements by sights of an inch. (E. Fleming).....n1447
 Texas topographic study begun by U. S. Geological Survey.....n404
 Topographic, precise levels, carried over large body of water.....n313
 Swimming pools:
 Midland beach, New York, inadequate design causes failure.....n383
 Open air, at Camp Dodge, Iowa. (L. N. Hunter).....n518
 Should pools be emptied in winter? Adams & Ruxton Construction Co.....n1858
 C. D. Hale.....n1068
 Switzerland, first form of transit measured by triangulation.....n63
 Sydney, Australia, rapid transit railway.....n645

T

Tackle blocks, large, hand made.....n659

Tanks:

Gasoline tanks, floating roof for.....n826
 Oil storage; roof built, in Belgium.....n522
 Oil storage, welded joints, Tulsa, Okla., is novel structure.....n988
 Steel storage tank, under test, in shovel.....n689
 Testing working models of ships, large tank for. (O. G. Colberg).....n139
 Tar cold patch, bars, and automobile license plates form mixer (J. S. Crandell).....n153
 Taxation:
 Mellon plan for reduction, American Institute of Consulting Engineers urge reduction.....n1033
 Write your Congressmen.....n959
 National Industrial Conference Board figures on taxes.....n965
 Testing machines:
 Accelerometer for measuring impact.....n26
 Extensometer, distant reading.....n27
 Strain-gage used to check bridge reinforcement.....n19

TESTS AND TESTING

Concrete, researches of American Society for testing materials.....n142
 Impact on culverts on roads.....n11
 Road, See Highways, Rates road, Pittsburgh road.....n132
 Hardness, new method of testing.....n132
 Ships, working models, large tank for testing. (O. Colberg).....n139
 Theaters:
 Wiesbaden, Germany, lessons from theater fire (Dr. G. Colberg).....n552
 (See Buildings, Theaters.)

- Tide gage, portable, for temporary use (G. R. Rude)..... *856
- Tide:
Hollow building tile..... *782
Number of sizes reduced..... *782
Tests (See U. S. Bureau of Standards).....

WATER WORKS

Chicago Sanitary District order against diversion of water, entered *331
 Denver, Colo., construction program *777
 Forestry on English water-works lands 188
 Merriamtown, N. J., one of oldest private water-works taken by city *1010, 1010
 Operation:
 Detroit, coal storage building for year's supply *10
 Iowa water-works men discuss dozen topics *780
 Omaha, Neb., mud-laden water causes trouble *361

Screens, revolving, for low-lift pumping station, Detroit filters (T. A. Leisen) *11
 St. Louis, Mo., extensions bonds, \$12,000,000 authorized *894
 St. Paul, Minn., votes \$5,500,000 bonds for water-works and sewers *155
 Truck trailer carrying tools for water-works emergencies *152

Welding:
 Oxy-acetylene welding in fabrication of steel structures *890

Wells:

Artesian wells, lugs welded on sections of casing *523
 Depth of water, pocket electrical device for measuring (J. M. C. Corlette) *414
 Water level indicator with telephone attachment *525
 Western Society of Engineers suggestions for engine terminal improvements 92

WILKES AND DOCKS

Ballantyne pier, Vancouver, B. C., flames *611
 Ballantyne pier, Vancouver, B. C., jet action in sluicing material delivered to fill on pier *610

Ballantyne pier, Vancouver, B. C., water increases delivery radius of steel handled in chutes *140
 San Francisco Bay, China Basin concrete caissons sunk in place for pier and seawall (F. G. White) *552
 Wheelbarrows, standards approved by committee *161
 Wilmette, Ill., Bahai Temple, concrete foundations *812
 Wilmington, N. C., concrete memorial bridge has attractive appearance *106
 Wilmington, N. C., demands a 30-ft channel to the sea 630
 Wire:
 Rust-proofing, new, "galvannealing" *700
 Wire mesh, turning clip for *325

WOOD PRESERVATION

Effect of wood preservative treatment tested in fungus bed *27
 U. S. Forest Service report, timber preservation in 1922 911
 Wood preservative in bored holes *139
 Worcester, Mass., city for build sewage treatment works (E. R. Perry) *832
 Wrench, self-adjusting *700

ENGINEERING NEWS-RECORD

DEVOTED TO CIVIL ENGINEERING
AND CONTRACTING

E. J. MEHREN, Editor
FRANK C. WIGHT, Managing Editor

Volume 91

NEW YORK, JULY 5, 1923

Number 1

Engineering News-Record is a consolidation of *Engineering News* and *Engineering Record*, effected in 1917.

Engineering News was founded in 1874 by George H. Frost, as the *Engineer and Surveyor*, which title subsequently became the *Engineer, Architect and Surveyor*, then *Engineering News* and *American Railway Journal* and finally, *Engineering News*, under the successive editorships of D. McN. Stauffer, Arthur M. Wellington and Charles Whiting Baker.

Engineering Record was established in 1877 by Henry C. Meyer as the *Plumber and Sanitary Engineer*. The name was subsequently changed to the *Sanitary Engineer, Engineering and Building Record* and, finally, to *Engineering Record*. During his ownership of the paper, Mr. Meyer was directly responsible for the editorial policy. John M. Goodell became editor in 1902, and was succeeded by E. J. Mehren.

The *Contractor* was consolidated with *Engineering News-Record* in 1918.

The staff of *Engineering News-Record* consists of
New York: E. J. Mehren, Editor; F. C. Wight, Managing Editor; M. N. Baker, F. E. Schmitt, R. K. Tomlin, Jr., C. S. Hill, J. W. Shaver and V. T. Boughton.

Chicago: W. W. DeBerard, E. E. R. Tratman.

San Francisco: N. A. Bowers.

An Extraordinary Structure

THE Los Angeles theater described in this issue is a remarkable example of reinforced-concrete design. There have been other theaters built of this material but so far as we can now find reference there has never been one with such long and large girders and trusses. Indeed the 126-ft. girders here are, we believe, the longest span concrete beams ever built. To Eastern engineers, fairly convenient to the structural steel mills, there will certainly arise doubts as to the economy of these huge beams and trusses in competition with a steel frame, but conditions on the West Coast are different and it is to be noted that the designing engineer says that his structure figured at less cost than one of steel. Then, too, there will be those who look askance on the tremendous concentration of steel in the large members and who will doubt the possibility of completely surrounding the rods with steel or of guaranteeing the interaction of steel and concrete once both are placed and under load. These, however, are merely questions; the Los Angeles engineers are answering them pragmatically. The Grauman theater design is made; the building is up; it works.

Engineering Societies as Public Advisers

EMPHASIS of the rôle of the engineering society as a watchdog of the public treasury, having wide duties and opportunities in relation to the economic aspect of public improvements, was the keynote of the presidential speech of C. A. Morse at the recent annual dinner of the Western Society of Engineers. As an unbiased expert the engineer is specially qualified to inform and advise the public on matters in which its vote is involved, so that reports or statements of society

committees may have—and should have—a large influence in public welfare. This opportunity of the engineering society was illustrated by Mr. Morse in regard to bond issues. In the first place there is the question of the issue itself, the vote on which is determined usually by personal opinion or prejudice as to the amount involved and the desirability of the improvement. Further, the public has little comprehension of the subsequent expense involved in maintenance and operation of public works. In fact, Mr. Morse considers that many a bond issue would be defeated if the voters understood that it covered first cost only and would entail heavy and continual future expense. One of the most important functions of an engineering society in taking an active part in public affairs, should be not only to check unwise expenditures for new improvements but also to promote proper maintenance and operation of existing works.

How To Do It

IN THE victory of the New York City engineers in saving High Bridge last week it was this attention to the economic side that apparently turned the tide, although the representatives of the societies are to be congratulated on their persistence in continued fighting for what appeared at times to be a lost cause. The Board of Estimate of the city was not much impressed with the sentimental regard that engineers and architects had for this early monument to American engineering skill but when they were shown that the new siphon required by the destruction of the bridge aqueduct plus the demolition itself would cost more than an artistic revision of the bridge, continuing thereon the aqueduct, they reversed their decision to tear High Bridge down. Engineering societies can get action if their cause is just and they know how to present it.

City Freight Belt Railways

REROUTING through freight traffic around large cities by means of loop or cut-off lines, in order to avoid congestion of busy local centers, has been extensively practiced in recent years, but the Flint belt line described in this issue serves two other purposes. In the first place, it will so relieve conditions on a line crossing the city at grade that costly track elevation projects are likely to be postponed indefinitely. In the second place it provides direct railway connection and switching service for a large industrial district established in the outlying part of the city by local interests in order to encourage the location of large manufacturing plants. Belt lines are an increasingly important feature in city and industrial development. L. F. Loree in his new book on "Railroad Freight Transportation," summarizes the situation well in the following sentences: "It seems quite certain that recent practice and experience is tending toward a recognition of the value of the belt line as one of the mechanical

elements of a comprehensive district clearing system. As a means for controlling and directing urban development along the rational lines of a wholesome city plan, the belt line appears to have been rather neglected. Of course, Chicago with its four concentric belt lines and New Orleans, Indianapolis and San Francisco are examples to the contrary. But this is especially true in the smaller but rapidly growing industrial centers. And here, if not in the older and larger cities, this feature of terminal organization might well receive further study and development."

New Opportunities

RATHER tardily, perhaps, but with the active approval of its membership the American Society for Testing Materials has decided to undertake the conscious stimulation and cultivation of research in materials. Heretofore its field has been limited quite narrowly to making specifications, and the committees have taken only incidental notice of the various deficiencies in knowledge of materials which their work revealed. It is true that many results of research were presented at the society's meetings, comprising the voluntary contributions of research investigators and the reports of studies carried out to clear up doubtful points about specifications. But all such papers had to edge their way into the program, so to say, and were not recognized as vital parts of the society's work. Moreover, when a committee encountered a new problem it had no encouragement to go into a study of this problem beyond what the purposes of the specification in hand required. But now that the development of new knowledge—study of materials and their behavior under various conditions, and of instruments and methods for observing this behavior—is established in recognized position as a main objective of the society's existence, new opportunities are opened up. Research will no longer be in the position of tagging along as a mere auxiliary of specification-making; it can thrive as an independent activity. To what extent this activity can or should be organized and systematized may yet need to be considered, though the achievements in the field of organized research are not particularly encouraging. Regardless of this detail, however, the society is entitled to congratulations on its forward-looking step. It has assumed a larger responsibility and assured itself a future of increased value to the world.

Efficiency Versus Tradition

WITH this hopeful reflection the observer of last week's meeting of the society is bound to couple a less optimistic thought. For a long time the society has enjoyed the distinction of having the longest and most unwieldy meetings among all our many technical societies, and it confirmed its claim to this title by the past week's meeting, which extended from Monday evening to the small hours of Saturday morning. With the help of a touch of very hot weather the meeting came near to wearing out the patience of many members in attendance—an effect not favorable to active thought and animated discussion. There has been in recent years a very marked slackening of activity on the meeting floor of the society. This has been coincident with increase in the length of the meetings; and while it would be unreasonable to argue herefrom a direct cause-and-effect connection, it would be just as unreasonable to deny that length of meeting had a contribu-

tory influence. The society's practice in the makeup of its programs has always been out of square with the principle and experience of other technical organizations, but it has been successful enough in the past to give color to the claim that the American Society for Testing Materials is quite exceptional in that its meeting is in effect a series of meetings, attended by successive relays of members. Even this fact, in so far as it is a fact, is of limited bearing on the matter, and cannot forever justify adherence to a precedent that may have been outlived. Continuing growth of its work, and increasing breadth and complexity of the interests concerned, demand that concentration and efficiency should be made prime ingredients of its meetings. These elements, however, are incompatible with programs so long as to tax the endurance and deaden discussion. Where efficiency demands, even tradition must yield.

For Improved Structural Knowledge

NOTABLE extension of the possibilities of strain measurement in engineering structures is in prospect if two new instruments brought to notice at the American Society for Testing Materials meeting last week carry out their full promise. One is a distant-reading extensometer, the other a highly sensitive and yet convenient and rugged instrument of the optical-lever type. Both were developed at the Bureau of Standards. A third instrument of equal importance, the photo-recording strain-gage of the Bureau of Public Roads, was described only a short time ago. Thus within the short space of a few months the art of structural investigation is enriched by a group of three new tools which add greatly to its resources. What they will accomplish is yet a matter of the future, but some indication of possibilities is given by their use for measuring stresses in airplane stay cables during flight, deformations in riveted joints, and impact in bridges, respectively. It is now possible, in other words, to follow the stress changes in inaccessible parts, to measure very minute, localized distortions, and to direct and record rapid changes of strain, even the high-speed vibrations occurring in bridges, all of which has not hitherto been practicable. This extension of our powers virtually assures important advance in structural engineering knowledge when the instruments are fully utilized.

Railroad Activities Ahead

NUMEROUS summarized programs of individual railroads which have been published in our news pages during the past few months indicate that the construction season of 1923 is to be exceptionally active in railroad work. As examples, there are the contemplated expenditures of \$50,000,000 by the Louisville & Nashville, \$41,000,000 by the Illinois Central, \$12,000,000 by the Philadelphia & Reading, \$6,000,000 by the Rock Island and \$3,000,000 each by the Nickel Plate and the Frisco lines. In most of these projects new construction and extension are relatively insignificant. Probably 85 or 90 per cent of the expenditure is for the improvement of existing lines by grade and line revision, additional main tracks and passing tracks, freight yards and yard extensions, engine terminals and various facilities. Furthermore, a large proportion of the small item of new line construction represents relief or cut-off lines built to increase traffic

capacity or operating efficiency rather than lines to open up new districts or develop new traffic resources. Part of this present and prospective activity is due to the necessity of making good the improvements deferred under war conditions, but the greater part is due to the growth of traffic which necessitates increase of facilities on existing lines rather than the extension of lines to produce additional traffic from new sections of settlement and cultivation. But although present attention is concentrated on improvement work the railway system is far from complete, and there is still future work for the pioneer and the locating engineer in new country, as well as for the engineer with the problem of the economic possibilities of improving operated railways.

To what extent the above improvement programs can be carried out during the present season will depend largely upon conditions of labor, wages and material supply and prices. But even if all the prospective work should be completed there is plenty more needing to be done as long as financial and political conditions will permit the railroads to proceed with adequate improvements and developments to bring the railroad system abreast of the country's needs.

Business Man or Administrator

WITH commendable promptness both the American Society of Civil Engineers and the Federated American Engineering Societies have put in motion investigations into the removal of Director Davis of the United States Reclamation Service. The issue is more than the injustice done to one engineer, however great that may be. The removal, or more particularly the appointment of Governor Davis, implies a charge against the whole engineering profession, to which the professional organizations must reply. And to formulate that reply those organizations must have all the facts. The Secretary of the Interior can hardly continue to maintain his reticence before the representatives of the engineers of the country, when they come before him for an explanation of the accusation that engineers are incapable of conducting an engineering organization.

Herein lies the seriousness of the Davis incident; that it may well be the beginning of a movement at Washington to make the government engineers merely the day-laborers of engineering work, the bosses of the concrete gangs, the instrument men of the surveys, the draftsmen and the estimators, leaving the direction of all of these to the so-called business man, who changes with each new administration or even with the political exigencies of the administration itself. It may mean a complete about-face from the ideal of engineering direction of government engineering work, which the profession knows itself competent to assume to the benefit of the country, and which would result from a properly organized department of public works.

Dr. Work, in one of his few announcements, defends himself with the statement that the work of the Reclamation Service has largely passed beyond the engineering stage and has become a business, that the chief engineer will continue to have charge of all engineering details but that this business operation must be in charge of a business man—the new commissioner at Washington being of that type. Passing over the obvious triteness of this glorification of the “business

man,” which name covers such a multitude of sins, it may be worth while to examine into this business of irrigation and to find out wherein the engineer is disqualified for it and the groceryman and banker qualified.

What does the Reclamation Service do? It designs and builds irrigation systems with government funds, it operates or supervises those systems after they are built for the benefit of settlers who pay the government for the land and the service at certain rates fixed by law. The design and construction are obviously engineering, the service is certainly engineering; there remains then only the matter of payment and the relations between the government and the settler. Is this more a matter for the business man than for the engineer? Is there anything inherent in the man who buys and sells which makes him better suited to deal with a group of farmers than a man who not only has designed and built the thing those farmers are using but also is in constant touch with their problems through the daily operation of that which they use?

It is not a “business man” that this business of irrigation calls for; it is an altogether different kind of person—an administrator. The Secretary's defense confuses these two terms. The engineer does not claim to be a “business man.” He does not buy things which he later sells at a profit, he does not take chances in the hope that a successful guess will outweigh in profits the losses from half-a-dozen unsuccessful ones. He is trained to learn facts and to proceed from those facts in orderly steps to a desired and desirable end. When in the individual he combines this method of practice with a knowledge of how to deal with men he becomes the ideal administrator, especially so when the field of his administration lies within the range of his specialized technical knowledge. The railroads are fast finding this out; is the government business so different that the rule does not hold? Is not the Secretary of the Interior acquainted with the Secretary of Commerce?

The question might be put to the Secretary in a somewhat more personal way. He is a doctor of medicine, a leading practitioner in that profession, we are assured; he has, in fact, been president of the American Medical Association. He also conducts a hospital, a matter which would seem to require a deal of so-called business ability. Does he think that it is necessary in the conduct of that hospital to bring in a business man to supervise his work and correct his judgment; would he insist on the appointment of another such business man to supervise the doctors in charge of the government hospitals? Or does he think that the profession of medicine is less technical than that of engineering and that the practitioners of the former have opportunities for administrative development not permitted the latter?

Doubtless the committees of the engineering societies will present some of these considerations to the Secretary. The day is past when the assumption that the engineer is a narrow specialist can be allowed to go unchallenged. As we said last week the whole morale of the government engineering service is imperilled, but more than that there is here an opportunity to take advantage of what bears all the earmarks of a political maneuver to give the people of the United States some understanding of the breadth of training and experience of the engineering profession.

Huge Concrete Girders and Trusses in New Theater

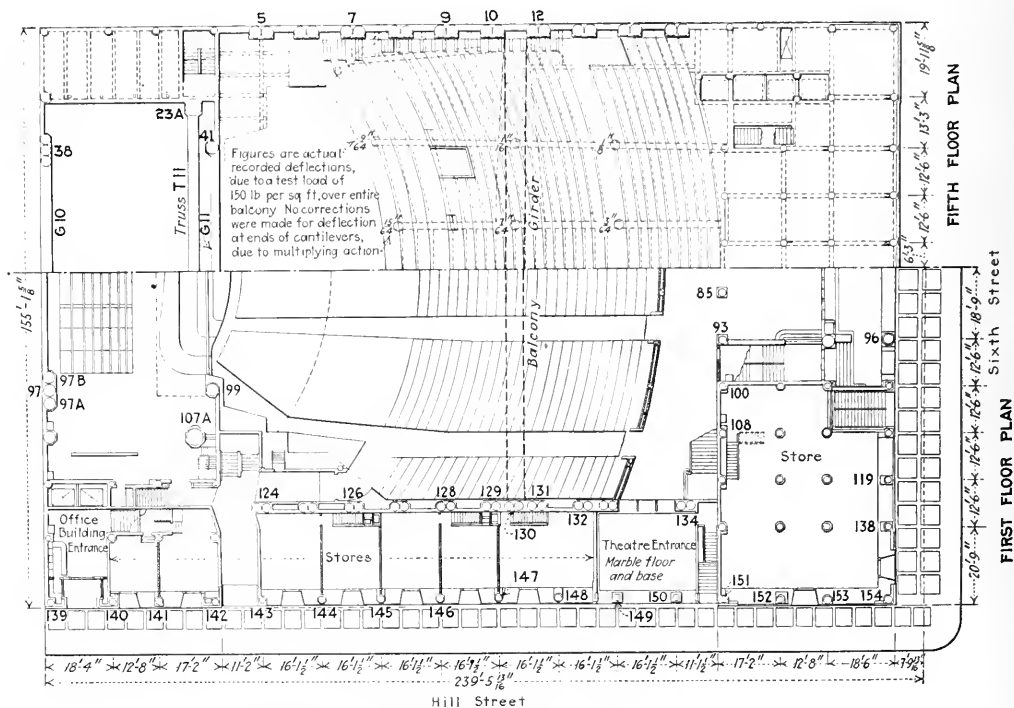

**Grauman's Theater and Office Building in Los Angeles Contains Reinforced-Concrete Roof Trusses
126-Ft. Span, Large Cantilever Truss Under Balcony and Girders Up to 126-Ft. Span**

By ROY C. MITCHELL

Engineer, Edwin Bergstrom, Architect, Los Angeles, Calif.

GRAUMAN'S Metropolitan theater and office building at Sixth and Hill Sts., Los Angeles, is a monumental piece of reinforced-concrete construction; other structures may have a larger volume of cubic content or number of cubic yards of concrete used, but from a standpoint of extraordinary structural design as varied as the component parts of a theater building and on the stupendous scale with which it was carried out, it has no equal in building construction. The main structural features are the ten 126-ft. span roof trusses; the

stories in height, with a frontage of 240 ft. on Hill St., 155 ft. on Sixth St., with an alley extending along the east side and the property line along the north side. Grauman's Theater will occupy the greater part of the building, with a seating capacity of 3,900. The offices, one tier deep along the Hill and Sixth St. sides, extend up to the seventh floor. From the seventh floor up the office portion of the building will be a U-shape plan, 48 ft. deep on each side. Above the seventh floor this office portion will be over the entire stage, along the

PLAN OF GRAUMAN'S THEATER SHOWING LOCATION OF TRUSSES AND HEAVY GIRDERS

cantilever balcony construction and the great 126-ft. girder which carries it; the framing over the main lobby with the marquise extending out 12 ft. from the building, with terra-cotta facing; the heavy girders over the stage supported by a large truss and girders over the proscenium arch and the large combined footing under the stage. There was used in this entire structure 2,700 tons of reinforcing steel, 84,000 cu. yd. of concrete, 127,000 bbl. of cement and 1,500,000 ft. of lumber.

This theater and office building, in general, is thirteen

alley side, extending out 48-ft. over the theater auditorium, which is supported on the reinforced-concrete roof trusses, and also along the entire Sixth St. frontage.

When the original plans were made, the building was to be a combination of structural steel and reinforced concrete. The main girders, trusses and framing over the stage were to be of structural steel on steel columns, but owing to the exorbitant price which was asked for the 1,500 tons of structural steel at that time, it made it almost prohibitive in going ahead with this building unless some other means could be devised for

UNDERSIDE OF BALCONY SHOWING CANTILEVER TRUSS SUPPORTS

Anchor arm of cantilever shown. Length of anchor arm 55 ft. Cantilever portion of truss 43 ft. 3 in.

CLOSE-UP OF COLUMNS UNDER ROOF TRUSSES

Note columns drawn together above the opening by foyer.

REINFORCING IN PLACE IN ROOF TRUSS

REINFORCED-CONCRETE TRUSS OVER PROSCENIUM

Span 87 ft. 6 in., height 29 ft. 6 in. Bottom chord, 34x39 in., with 72 1½-in. bars.

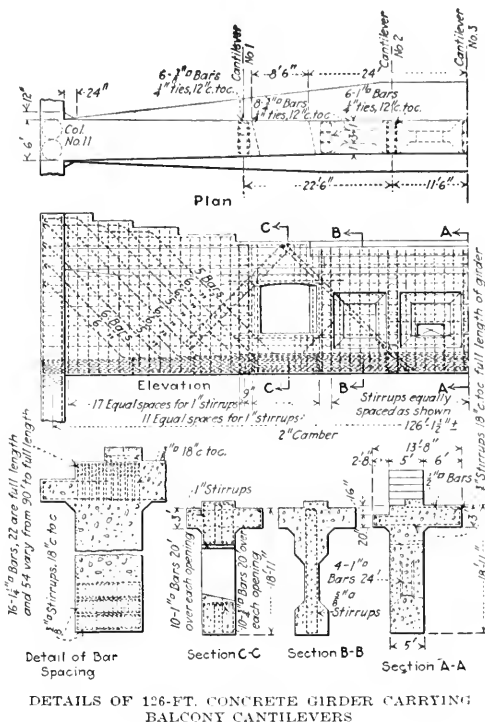

STEEL IN BOTTOM OF BALCONY GIRDER

In this lower section are 204 1-in. bars across a width of 5 ft. and extending up about 3 ft. Outside layer of steel is outside of part of the stirrups.

UNDERSIDE OF ROOF TRUSSES

Note the widening of chord near support.

The floor system on the balcony was next placed; then the first floor in the auditorium and stage was built.

After the removal of the forms from the balcony a test was made by the city building department. This consisted in loading the entire balcony with a load equal to twice the designed live-load, which was 75 lb. per square foot. This test was made by piling a uniform load of 150 lb. per square foot consisting of earth, sand, cement and lumber over the entire balcony, equal to a load of 1,500,000 lb. This load is equal to seven times the weight of the people that can be seated in the balcony. Before this test load was placed, triggers to measure the deflection were set up at the end of each

cantilever and under four points on the girder, also under the anchor arm of each cantilever. This test showed a minimum deflection of $\frac{3}{8}$ in. and a maximum deflection of $\frac{1}{4}$ in. on the four anchor arms; a minimum deflection of $\frac{3}{8}$ in. and a maximum deflection of $\frac{1}{4}$ in. in the balcony girder, and a minimum deflection of $\frac{3}{8}$ in. at the front end of the cantilevers. Close examination was made for cracks while this test load was in place but no cracks could be found at any point, and on removing the load the entire balcony came back to its original position.

The settlement and shrinkage of the falsework which supported the roof trusses up to the time of starting to pour the concrete was $\frac{1}{8}$ in. During the pouring of the bottom chord of the truss an additional settlement of $\frac{1}{8}$ in. took place. Upon removing the supports from under these trusses, after sixty days, a deflection of $\frac{3}{8}$ to $\frac{1}{2}$ in. took place; also a horizontal deflection of $\frac{1}{8}$ in. in the long columns next to the alley side.

The unit stresses used on all this work are those required by the Joint Committee on Concrete and Reinforced Concrete, 1921. No attempt was made to use any high stresses or extra mixing of the concrete, the concrete being one part of cement, two and one-half parts of washed sand and three and one-half parts of $\frac{3}{4}$ -in. rock. All cement and steel were tested. All the concrete was mixed in 1-yd. batch mixers, hoisted and placed from buggies and wheelbarrows. No spouting of concrete was allowed. Particular attention was paid to the mixing of this concrete to see that it was of a consistency that would properly flow.

Two concrete mixing plants in the basement of the building consisted of storing bins, conveyors and elevators for the sand, rock and cement with a capacity to permit of pouring any two of the largest units on the building at one continuous pour without depending on material to be delivered. Extra precaution was taken so as to guard against a breakdown of this mixing plant by having duplicate parts on hand for both mixers, as well as two separate sources of electrical power.

The forms used consisted of ordinary construction of 2x4's and $\frac{3}{4}$ -in. form lumber. The falsework was built up to a point approximately 4 ft. below the bottom of the trusses or girders and was then covered with a 2-in. plank floor. On top of this, 4x4's set on wedges were used to support the forms for trusses and girders. The ten trusses over the auditorium were built up in pairs. This permitted building the sides of two ad-

jacent trusses and formwork before placing the steel. A full-sized template of the trusses was first laid out on top of the falsework; boxes were made for the inside and were later put in place after the steel had been erected. The forms were allowed to remain in place for sixty days after the concrete was poured. However, a small portion at each end was taken down at the end of thirty days.

In each one of these large trusses or girders the concrete was all placed in one continuous pour. On the roof trusses each truss was poured in a continuous run of about seven hours on ten consecutive days. No attempt was made to hurry. Concreting was started by pouring the bottom chord full at one end and gradually working the concrete the full length of the bottom chord; then the diagonal members were poured and finally the top chord and roof.

The construction of the balcony girders, cantilever trusses and the framing over the stage was carried out in practically the same way as for the roof truss.

The Winter Construction Co. was the general contractor. The structural design was made by the writer in the office of Edwin Bergstrom, the architect.

Waterpower Resources of Russia Concentrated in Asia

Vast Resources in Asiatic Russia—Limited Ones in Europe—Possible Effect on Centers of Population

By I. GUTMANN

THE COLOSSAL plans of the Soviet Government for the electrification of Russian industry and transportation through the development of the hydraulic resources of Russia cannot be studied intelligently until one has an idea of the magnitude, availability, and geographical distribution of these resources. Such detailed quantitative data are now available through their publication by Prof. A. Deysha in the *Vyestnik Inzhenerov* of Moscow, the official organ of the "All-Russian Association (Union) of Engineers." A brief discussion of these data is believed to be timely.

The accompanying table, giving an abstract of these data, does not include streams or portions of streams which may be covered with ice more than 200 days in the year, or whose slope is less than 1 in 3,000. Catchment areas lying higher than 2,000 meters above sea level have also been excluded. The column headed "concentration" gives the minimum horsepower per square mile of contributing catchment area and serves roughly as an index of the availability and cost of development of the hydraulic energy of the basin.

For comparison, the Mississippi has a minimum of 5,500,000 hp. at a concentration of 4.5 hp. per sq.mi., the St. Lawrence, to the Canadian line, has nearly the same number of hp. at a concentration of about 18 hp. per sq.mi.; and the average "concentration" of potential power in the state of Washington is about 70 hp. per sq.mi. It should also be noted that the United States, with area only one-third that of Russia, exceeds the total potential hydraulic power of Russia by a half.

It will be observed that European Russia, which has a population of over 100,000,000, or about 80 per cent of the total population of Russia, is quite poor in hy-

draulic power resources. Indeed on an area which is about three-fifths of the size of the United States there is only 586,000 hp. or just about one-fiftieth of the potential water powers of the United States. The state of North Carolina has as much hydraulic energy as the whole of European Russia, California has six times as much and even Nevada and South Dakota are comparatively richer in hydraulic power resources than European Russia. The Russian territories which are rich in hydraulic power—Caucasia, south-eastern Si-

DISTRIBUTION OF THE WATERPOWER RESOURCES OF EUROPEAN AND ASIATIC RUSSIA

Region or Basin	Concentration Hp. per Sq. Mi.	Hp.	Total Hp.
European Russia	0.26		586,000
Caucasia:			7,715,000
Black Sea slope	450.00	2,285,000	
Northern Caucasia	106.00	3,330,000	
Caspian slope	54.00	400,000	
Southern Caucasia	23.00	1,700,000	
Ural	4.70		923,000
Russian Turkestan:			1,550,000
Syr Darya	17.00	1,550,000	
Southern Siberia:			5,055,000
Irish		725,000	
Yenisey	8.00	3,565,000	
Lena		765,000	
South-eastern Siberia or Amur Region:			3,130,000
Zeya	23.00	2,000,000	
Bureya	34.00	970,000	
Ussury	2.10	160,000	
Kamchatka	21.00		410,000
Total for Russia		about 20,000,000 hp.	

beria, Kamchatka, etc.—are very remote from the centers of population and industry which are in European Russia, and the power which may be developed in these territories cannot be used for the electrification of present day Russian production and transportation any more than the water powers of California and Oregon can be used for the electrification of industry and transportation in Illinois or New York.

In other words, industry and transportation in Russia proper may be electrified, by the utilization of the hydraulic resources, only to a very limited extent.

For the present at least the enormous quantities of hydro-electric energy which can be developed in Caucasia and Siberia will have to be consumed within or near the regions where they may be generated. Fortunately these regions are rich in minerals, lumber, livestock and agricultural resources, and the power developed in them may be applied to mining, manufacturing, irrigation and agriculture. Caucasia which besides its immense hydraulic resources has also rich oil fields and a wonderful climate, may rival California in its development; the Amur region in southeastern Siberia may surpass British Columbia; while southern Siberia may develop like Montana and Alberta.

These rich sections of the Russian Republic promise to become great centers of production which may bring about a shift in the centroid of population towards the periphery, southwards and eastwards—chiefly eastwards—towards the Pacific.

Irrigation and Drainage Have Helped Italy

In the course of a recent address on Economic Progress in Italy before the Engineer's Club of Minneapolis, Dr. Jeremiah W. Jenks, who spent six months abroad late in 1922, said: "Italy of all countries in Europe has made most progress since the war. This is especially notable in agriculture, which is now in better condition than before the war, principally because the Italian government invested in drainage and irrigation projects.

Coal Storage for Year's Supply for Detroit Water-Works

Duplicate Coal-Handling Equipment Gives Continuity of Service—Dragline Scrapers Reclaim Coal to Feed Hoppers

CONTINUITY of operation of the Detroit water-works pumping stations is assured by duplication of equipment and by summer storage of sufficient coal to last throughout the remainder of the year. Coal is purchased and shipped by water during the summer to secure an adequate supply at reasonable cost. The present installation, completed in 1922, was designed to crush and store coal in the 25,000-ton shed at the rate of 100 tons per hour and to supply intermittently any one of twelve 400-hp. horizontal water-tube boilers equipped with underfeed stokers. A crane unloads into a crusher the coal from vessels traversing 2,000 ft. of canal from the Detroit River. The crushed coal is

LONG LOW 25,000-TON COAL STORAGE BUILDING WITH DUPLICATE BOILER HOUSES AND STACKS IN REAR

City-owned canal for coal delivery by vessel connects with Detroit River 2,000 ft. away. Pent house over 175-ton coal bunker is just below one of the cupolas on pumping station 1. In the right rear is pumping station 2. In extreme left rear is obsolete water tower. Crane unloads coal from vessels to crusher. Inclined belt 1 (just back of smoke of crane engine) delivers to end of belt 2 running entire length of storage house.

delivered by an inclined belt to the end of a second belt conveying it the length of the storage house.

As shown in the sketch the boiler house is in effect two distinct installations, each with its own chimney, boilers, breechings, feed-water heaters and pumps. The boilers are grouped in batteries of three on either side of each of the two 150-ft. chimneys. The units are separated by two fire walls with a shop space of 20 ft. intervening. It was also considered best to keep the coal and ash-handling systems separate so that failure of one might not interfere with the functioning of the other.

The source of supply is the Toledo pool of Ohio and Pennsylvania run-of-mine bituminous coal. Barges are docked in the department's canal and unloaded by clam-shell bucket and crane. Coal is dumped into a hopper with a reciprocating feeder and crushed by a 30-in. double-roll crusher fitted with replaceable steel teeth. The hopper, crusher and lower end of a 24-in. belt conveyor together with motors and interlocking control are housed in a brick crusher tower which supports the lower end of a reinforced-concrete bridge inclosing the belt conveyor. On its journey to the storage building the coal is weighed as the belt passes over an integrating weightometer. A 24-in. horizontal belt receives the coal where it enters the building and distributes it along the south wall by means of an automatic self-propelled and reversing tripper.

RELATION OF COAL AND ASH-HANDLING EQUIPMENT TO DUPLICATE BOILER HOUSES AND PUMPING STATION 1

The coal storage building, 320 ft. long and 180 ft. wide, divided by a central cross-wall, is constructed with reinforced-concrete retaining walls for a height of 20 ft. From the top of the concrete up to the parapet is ordinary brick curtain wall construction. The entire roof area of 10-ft. span reinforced-concrete slabs is supported on a system of Pratt trusses and girder trusses. Only two concrete-incased steel columns in each half of the building obstruct the clear area. Coal is stored to a depth of 20 ft. and reclaimed by means of 1,000-lb. capacity drag scrapers. A complete scraper system with power unit is provided in each half of the building. Either scraper will store coal about as fast as delivered from the 24-in. belt, leaving the other for use in reclaiming the daily supply to hoppers installed centrally in the north side of the building. These hoppers with feeders and the boot of a bucket elevator are inclosed in a concrete pit. The coal is elevated and stored in a 19-ft. diameter cylindrical steel bunker of 175-ton capacity, located centrally between the east and west boiler house units, directly over the line of travel of the motor-driven 1-ton capacity weigh larries feeding the stoker hoppers. It is of interest to note that 20,000 tons of coal were weighed in over the weightometer during a certain period last year and that the coal weighed out on the larry scales checked this figure by less than 50 tons; the discrepancy no doubt was largely due to evaporation of the moisture.

At Detroit, under-water storage is not practicable because of the cold winters, and no other special provisions were made to prevent fires. After various schemes were considered for combatting possible fires from spontaneous combustion, it was decided that barricading the two handcar track doors and flooding the entire building with water to a depth of 4 or 5 ft. would quench any fire that a trench cut through the affected area with drag scrapers would not control.

The ash-handling equipment is designed as a separate unit for each boiler house. One unit is located at the east and one at the west end of the plant, easily accessible to motor trucks. Ashes are drawn by hand from the boiler ash pits into small 18-cu.ft. ash cars moved by one man along a 24-in. gage track and dumped into the 20-cu.ft. bucket of the skip hoist. The mechanism is operated by push-button control to elevate the bucket and discharge ashes into a 14-ft. diameter ash bunker having a capacity of 2,500 cu.ft. A balanced duplex gate in the bottom cone of the bunker, about

9 ft. from the ground level, provides for loading the ashes into a motor truck.

The installation has proved satisfactory in every way, according to the engineers. W. H. Mueller, of Detroit, executed the contract for the coal-storage building. The coal-handling equipment was installed by the Guarantee Construction Co., of New York, and the ash-handling equipment by the Palmer Bee Co., of Detroit. The design and construction of this work was carried out under the general direction of George H. Fenkell, superintendent and general manager, and Theodore A. Leisen, consulting engineer.

Planned Publicity Aids Missouri Road Program

Signs Describing Operation Placed on New Projects—Located State Routes Marked Before Road Is Improved

A NECESSARY adjunct of state road building at the present time is well organized publicity. In Missouri the State Highway Commission, realizing the necessity of gaining the confidence of the citizens in the commission, established a policy which was expressed in formal resolution "to take the people of the state into the confidence of the Commission." The result has been that the comprehensive plan of building 7,643 miles of highways in the state has withstood the onslaughts of politicians and has weathered a session

MARKERS PLACED ON LOCATED STATE ROUTES

signs and this will be followed by the erection of another 100. It is hoped to have at least one in each of the 114 counties in the state. The experiment is not a costly one considering the value the commission believes it receives therefrom, and, since building roads is an operation of which the general public knows little in detail, the information serves a splendid purpose by keeping the entire state advised of the progress towards attaining a condition of perfection in highways.

Another essential feature of the publicity campaign is the erection of road markers upon the designated highways of the state. There are some 90 of these numbered routes traversing the state in both directions, with a large number of shorter stretches connecting the important primary routes. Each one of these highways carries its distinctive number. Pending the construction of all highways these markers are placed on the decided routes between the points named in the law and should the surveys and actual construction follow a different route, they will be reset after the roadway has been completed.

Another method used to enlighten citizens on the work of building roads, is the transmission at frequent intervals of short news stories to the leading weekly papers of the state. It has been found that so much interest is manifested in highway construction that the county newspaper is always anxious to secure reliable data that it can give to its subscribers. There are some 200 or more newspapers in the state that regularly print this matter which is prepared in the office of the commission by a trained newspaper man. This publicity goes into the rural communities and carries information to those places where it is, no doubt, most needed.

Tests Show High Impact on Culverts

Tests of the transmission of impact from road surfaces downward through the fill to culverts have been carried out at Iowa State College. Prof. Anson Marston states that impacts as high as 100 per cent of the static effect of the moving load may occur where the thickness of cover over the culvert does not exceed 2 ft. This experimental showing, moreover, is verified by field experience with pipe culverts under thin cover. In one case, many culverts broke under shallow fills.

PROJECT-INFORMATION SIGN-BOARD

of the legislature which was so influenced by public sentiment that all efforts to change the state law were effectively throttled.

One of the publicity methods which has given much satisfaction throughout the state has been the erection on all large projects in the various counties of a sign-board shown by the accompanying illustration. This sign carries at the top the announcement that the project is being constructed under the direction of the Missouri State Highway Commission, followed by the statement that "Road building is a process of which the successive steps are grading, draining, constructing foundation and surfacing. After construction, systematic maintenance is essential on all types of roads." This is followed by the project number, the name of the county, the length of road to be built, the cost, the material to be used and the name of the engineer in charge and of the division engineer. This sign is erected on the right-of-way at some point along the project and may be seen by all travelers.

So far, there have been erected 100 of these large

Belt Line and Industry District at Flint, Mich.

Pere Marquette R.R. Builds Loop to Detour Freight Traffic and Serve Large Outlying Industries

AN 8½-mile line now nearing completion by the Pere Marquette R.R. at Flint, Mich., will not only divert through freight traffic from the main line which traverses the city but will serve also to develop a large industrial and manufacturing district established by the city. In addition, this improvement is likely to postpone indefinitely a move for the more expensive work of elevating the main line in order to eliminate street crossings at grade, since it is the freight trains which are the main cause of complaint in obstructing traffic.

From Fig. 1 it will be seen that the main line runs practically north and south in a wide loop through the city, and near the center of the business section it has a grade crossing with the Grand Trunk Ry. The Detroit

tion and a union passenger station for steam railways and electric interurban lines, were included in the suggested improvement, but it was shown that the diversion of freight traffic from city streets was of more immediate importance.

War conditions delayed the proposed development, but in 1921 the Chamber of Commerce agitated the matter, the city limits were extended north and east, an area of about 1,000 acres within the new eastern limits was secured by local interests for the industrial district, and a right-of-way for an 8½-mile belt line was also obtained. Negotiations for the construction and operation of this line were entered into with the Pere Marquette R.R. and that company offered to undertake the work if the right-of-way was provided. The necessary land was then donated to that company with the understanding that the trackage would be available for any railroad which might desire to use it. Later, however, the railway company bought the line for use as a freight cut-off. The company will operate all industrial switching movements and will provide for interchange with other roads. A structural steel plant and two or three

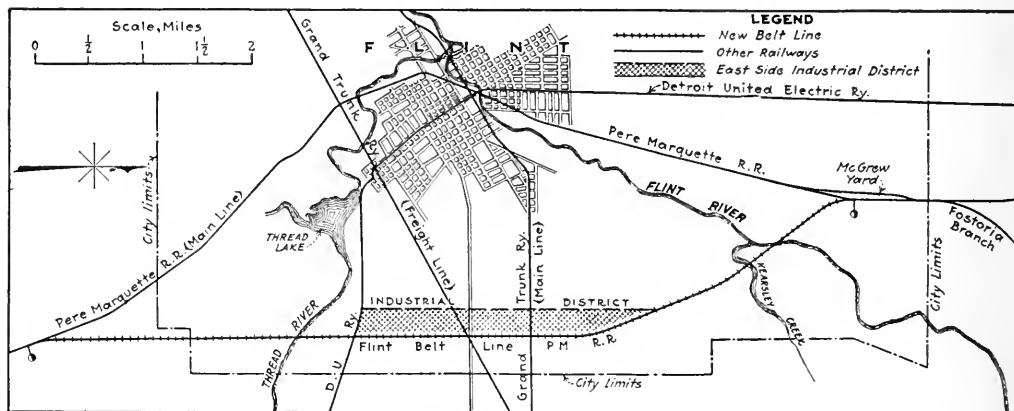

FIG. 1—BELT LINE OF PERE MARQUETTE AT FLINT

United Electric Ry. operates an interurban passenger and freight service through the city. All these lines are at street grade. About twenty years ago the Grand Trunk Ry. built a freight loop or belt line which runs south of the central portion of the city and thus keeps its through traffic away from the business district. In recent years, however, the city has been built up to this line. On the Pere Marquette R.R. there are about eight passenger trains daily, but the interruption to street traffic comes mainly from the long and heavy freight trains moving at slow speed. Fire equipment has been halted occasionally in this way, with consequent public complaint and demand for grade separation.

A project for an east side industrial district with railway communication, in order to provide systematically for the commercial expansion of the city, was included in a report made to the City Plan Commission in 1917, by Bion J. Arnold, consulting engineer, Chicago, and John Nolen, city planning expert, Boston. For railway service it was proposed to have a municipal line extended through this district, to be operated either by the city or by some connecting line under lease, with the provision that free use of the line should be accorded to all railways entering the city. Track eleva-

tion and a union passenger station for steam railways and electric interurban lines, were included in the suggested improvement, but it was shown that the diversion of freight traffic from city streets was of more immediate importance.

For the first five miles of the belt line the earthwork is light, but for 3½ miles at the north end it is much heavier, the line crossing the Flint River valley and ascending to a higher plateau. Two long fills of about 130,000 cu.yd. on the south and 50,000 cu.yd. on the north form the approaches to the Flint River bridge. The total excavation on the line is about 280,000 cu.yd. A roadbed width of 20 ft. is given on fills and 24 ft. on cuts. In fills the quantity is increased by raising 10 per cent above subgrade to allow for settlement and subsidence. The maximum grade is 0.3 per cent and the sharpest curves are of two degrees.

Track is laid with 90-lb. rails on hardwood ties treated by the zinc-cresote process. Interlocking plants will be provided at the intersections of the Grand Trunk Ry. and the Detroit United Ry. At the north end of the line is the McGraw yard, where cars to and from local points and the industrial district are cut out and assembled.

In making the large fills, framed bents were used for the temporary trestles as it was cheaper to buy timber than to drive piles. Filling was handled by 8-car

FIG. 2.—ABUTMENT WITH ARCHED OPENINGS

trains of gondola cars having the sides formed by panels hinged at the top, these cars averaging loads of 25 cu. yd. When the train reached a fill, with the locomotive and unloader car at the rear end, a car with unloader plow in place was coupled to the head end. The hook of the plow cable on the drum in the rear car was then attached to a derrick beside the track and the train pulled ahead until the cable was strung along the train and hooked to the plow on the head car. The train was then backed down onto the trestle and the unloader engine hauled the plow through the cars, men keeping ahead of it to release the latches of the side doors. When the empty train had pulled off the trestle, the car with plow (next to the unloader car) was cut off and left to be attached to the head of the next train.

The two principal bridges are those over the Flint River and Kearsley Creek (Fig. 2), both of which are plate girder structures on concrete piers and abutments. The former has two 70-ft. spans and the latter has one 80-ft. and two 60-ft. spans. The abutments are of very heavy design and have arched openings so that the end slope of the fill extends through the abutment, which is thus largely embedded in the earth so that the pressure against it is equalized. Under the surface sand and clay is a deep bed of hard blue clay in which foundation piles could not be driven and it was even difficult to drive sharpened sheet piles for the cofferdams. The piers were built in this clay and built up as concrete monoliths. All foundations and substructures are built for double track, with single track spans at present. All bridges of the line are designed for Cooper's E-60 loading.

The Dominion Construction Co., Niles, Mich., has the contract for the entire line and has operated a force of about a hundred men, working 10-hour days and accommodated in two camps. The line was laid out and built under the direction of A. L. Grandy, chief engineer (now assistant to president and general manager), Pere Marquette R.R., and J. Tuthill, assistant chief engineer, with Frank Manning as resident engineer in charge. The total cost will be about \$800,000 and it is expected to have the line completed by the summer of 1923.

Tests a New Locomotive Booster

AN EXPERIMENT of particular interest to railway mechanical men, and of general interest to all engineers interested in railroad operation, is now being carried on by the Delaware & Hudson Ry. on its Susquehanna division. It consists in the trial of a new type of booster for use on the tenders of locomotives, known as the M. & L. booster. Heretofore the only boosters in actual operation were installed as trailers on the locomotives. There are at present about 1,000 of this type in use, some of them for nearly three years.

On June 5 the D. & H. company gave a demonstration of their new booster in actual operation over a section of track between Central Bridge and Delanson, a distance of 9.5 miles and up an 0.8 per cent compensated grade $5\frac{1}{2}$ miles long. An inspection train was run on a track parallel to the one on which the locomotive with the new booster was operating, so that it was possible at all times to observe its performance.

The locomotive was a consolidation type with a rating of 1885 adjusted tons. For the purpose of this test the rating was increased by 591 tons, or 31.35 per cent, a total of 36 loaded cars. To demonstrate the capacity of the locomotive the train was stopped on the middle of the hill. Without the booster the locomotive could not start the train, but when it was cut in the train was started again without difficulty.

This booster was designed by Col. J. T. Loree, general manager, and Maj. J. A. McGrew, general superintendent of equipment, both of the Delaware & Hudson Co. It consists of a simple two-cylinder engine with 12 x 10-in. cylinders geared to the rear axle of a pedestal type four-wheel truck of the locomotive tender. Power is transmitted to the forward axle of the truck by side rods. The engine is so arranged that it can be thrown into mesh by a bell crank operated by a piston impelled by steam from the line supplying the booster engine.

The advantage of this type of booster over the type now in general use on locomotives is that it makes use of the weight of the tender in gaining tractive effort, and does not increase the weight of the locomotive. This feature is of particular advantage on lines where the concentrated weight of the locomotive has about reached the carrying capacity of some of the bridges. It is lighter in weight, and has developed a higher efficiency by about 15 per cent than most of the boosters now in operation.

The first booster of this type constructed under the patent of Messrs. Loree and McGrew was made at the D. & H. shops. The booster tested on June 5 was manufactured under the same patent by the Baker Manufacturing Co. of Saratoga Springs. The D. & H. company considers that this booster has gotten beyond the experimental stage, and it is reported to have placed an order with the Baker Manufacturing Co. for 100 more.

Typoid Fever a Compensable Accident

Typhoid fever contracted by a hotel employee "as the result of drinking impure well water furnished by the hotel," states *Public Health Reports* for June 8, 1923, "has been held compensable as an accident within the meaning of the Workmen's Compensation Act by the Supreme Court of Michigan." (*Frankamp v. Fordney Hotel et al.*, 193 N. W. 204.)

Revolving Screens for Low-Lift Pumping Station, Detroit Filters

Primary Mission to Intercept Floating and Slush Ice—Adhering Matter Flushed Into Trough Leading to Sewer

BY THEODORE A. LEISEN

Consulting Engineer, Department of Water Supply,
Detroit, Mich.

IN THE OPERATION of the new Detroit filtration plant (see *Engineering News-Record*, May 17, p. 860) the water will be raised from 25 to 30 ft. for delivery to the coagulation basins. The low-lift pumping station, constructed for this purpose, is equipped with five electrically-operated centrifugal pumps, and one of the factors of special interest in this station is the system of revolving screens which intercept the water before it reaches the pumps.

The water from the Detroit River is conveyed to the station through a 10-ft. tunnel and conduit, and at the southerly or influent end of the station it enters a chamber 31 ft. wide by 59 ft. long, the bottom of which

FIG. 1—INTAKE SIDE OF REVOLVING SCREENS
Each set is operated by separate 5-hp. motor.

is slightly lower than the invert of the tunnel, and about 35 ft. below the surface of the ground. The screens are in a perpendicular plane, centrally located across this chamber on its longer axis. Beyond the screen chamber a suction well 11 ft. deep and 26 ft. wide extends for the full length of the station, with the pumps located on the floor immediately above this suction well or conduit.

There are seven sets of revolving screens, operated by a separate 5-hp. electric motor, providing a speed of 10 ft. per minute. Each screen consists of thirty-eight panels 24 in. wide by 72 in. long, interlocking along the upper and lower edges, and in close contact at the ends with the stationary guides. The panel frames are made of 2x2-in. steel angles with a 3-in. projecting lip or bucket at the bottom upstream face of each panel. The screening element, which is bolted to the panel frames, consists of 14-gage copper wire, three meshes to the inch, making the net openings approximately $\frac{1}{4}$ in. square. These panels are secured to endless link chains revolving around upper and lower sets of sprocket wheels, with the lower end passing through a special shoe and the upper end projecting 6 ft. above the operating floor, the total distance between upper and lower sprocket-wheel shafts being 31 ft.

FIG. 2—DISCHARGE SIDE OF SCREENS DURING ERECTION
The 1-in. mesh screen panels are 2 ft. wide by 6 ft. long and the total opening interposed across the screen chamber is six times the area of the inlet tunnel.

Under normal conditions of operation the screens are submerged to a depth of 24 ft., and the net water area of openings in the seven sets of screens is approximately 500 sq.ft. or over six times the cross-sectional area of the intake tunnel, resulting in a very low velocity in the passage of the water through the screens.

The primary mission of the screens was to intercept all floating or slush ice coming through the tunnel, and to prevent the permanent formation of frazil or needle ice on the surface of the screens, but incidentally they serve also to prevent the passage of fish and all floating debris. All material adhering to the face of the screens or caught on the projecting lip or bucket is washed off by means of a water spray. A perforated pipe placed back of the screen below the upper sprocket wheel, where the downward passage begins, supplied by water under 60-lb. pressure, washes all adhering matter off into a trough connected to a sewer. Warm water and steam are provided for use in the event of persistent ice formation.

The screens, which were built by the Link-Belt Co., were in use throughout the past winter, proving entirely satisfactory and clearly demonstrating their value.

Canadian Good Roads Association Meets

The tenth annual convention of the Canadian Good Roads Association was held at the Royal Connaught Hotel, Hamilton, Ont., June 11-13 with a large attendance of delegates representing every province of Canada, and including many cabinet ministers. Among the more prominent of those who delivered addresses or read papers were Hon. J. L. Perron, Minister of Roads for Quebec Province; Hon. H. Cockshutt, Lieut. Governor of Ontario; Hon. E. H. Armstrong, Premier of Nova Scotia; Hon. F. C. Biggs, Minister of Public-Works for Ontario; Hon. J. D. MacLean, Provincial Secretary of British Columbia; D. M. Hill, Provincial Highway Engineer for New Brunswick; Hon. J. P. Veniot, Premier of New Brunswick, and A. W. Campbell, Dominion Commissioner of Highways. Strong appeals were made for a continuance of federal aid in highway construction. The following officers were elected: honorary president, Hon. J. L. Perron, Quebec; president, Russell T. Kelley, Hamilton; first vice-president, Hon. Frank C. Biggs, Ontario; second vice-president, A. McGillivray, Manitoba; secretary-treasurer, George McNamee, Montreal.

Calumet Harbor Advocated for Chicago

THE Interstate Harbor Commission organized by the states of Illinois and Indiana to report upon the so-called "Illiana" project for a harbor on Lake Michigan at the state line and also utilizing Wolf Lake, has reported adversely to this project. In view of the large areas of undeveloped harbor sites, the uncertainty of early development of the St. Lawrence waterway and the enormous cost of \$400,000,000 estimated for the Illiana harbor, it is recommended that no further action be taken at this time, but that the waters of Wolf Lake be retained for possible further use. On the other hand, the development of a harbor in Lake Calumet is recommended, as approved by the War Department.

A general review of the Chicago harbor and waterway situation is given in the commission's report, and is explained by the accompanying map. It is pointed out that the Great Lakes and St. Lawrence waterway

5. Development and use of the unoccupied lands inland from Indiana Harbor, Ind.

6. Improvement of the Little Calumet River and the Calumet-Sag canal of the Sanitary District of Chicago as demands may require.

7. All terminal developments and operations to be under the supervision of the Illinois Division of Waterways and some appropriate state agency for Indiana.

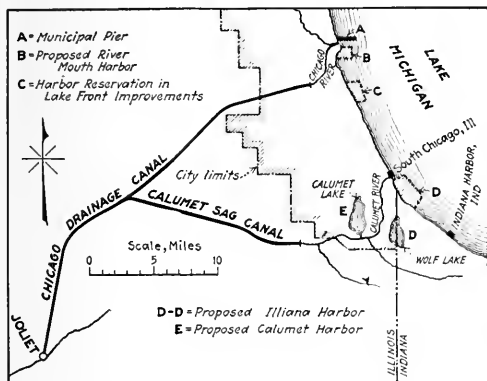

Boston Metropolitan Planning Commission Created

A DIVISION of Metropolitan Planning within the Metropolitan District Commission of Massachusetts is created by Chap. 339 Acts of 1923 of that state. The commission has comprehensive duties in the way of investigations, reports and advice on transportation in all its phases and in its various relations to local and metropolitan planning.

The commission is to consist of seven members of whom three, to serve without pay, are to be appointed by the Governor, with the approval of the Council, for five-year terms, while one is to be an associate commissioner of the Metropolitan District Commission (which now has charge of water supply, sewerage and parks of the Metropolitan District); one a commissioner of the Transit Department of the City of Boston; one an associate commissioner of the State Department of Public Works (which has charge of highways, waterways and lands), and one a commissioner of the Department of Public Utilities. Each of the four ex-officio members is to be designated by the head of his department. The chairman of the division is to be named by the governor. The division is required to report annually to the Legislature and to submit annually to the budget commissioner an estimate of its expenses for the ensuing year. This estimate is limited to \$25,000 annually and is subject to legislative approval.

The section of the act stating various duties follows:

Said division shall investigate transportation service and facilities within the metropolitan district, which shall consist of all the cities and towns in either of the metropolitan sewer districts, the metropolitan water district or the metropolitan parks district, and the co-ordination thereof upon highways, roads, bridges, waterways, railroads, street railways and other arteries of traffic; what, if any, use of existing facilities of carriers by one or more of such methods can and should be made by others; the manner of effecting such co-relationship and what improvements and new facilities should be provided for a comprehensive and co-ordinated development of transportation for said district; and the relation of such service to the general service rendered by all highways, roads, bridges, waterways, railroads, street railways and other arteries of traffic in the commonwealth so far as the division deems it necessary or desirable. It shall confer with the local planning agencies in the district with regard to such projects as are not of an exclusively local character. It shall recommend the method of executing and paying for the same, and shall make such maps, plans and estimates of cost as may be needed for its investigations and reports, and may employ such assistants therefor as it deems necessary. The various other departments, boards, and divisions of the commonwealth, the public trustees, respectively, of the Boston Elevated Railway Co. and of the Eastern Massachusetts Street Railway Co., the street commissioners, planning boards and other officials of cities and towns comprising said district, and the various public utilities operating therein may, and upon request of the division shall, consult with it and furnish all facts and information requested within their knowledge and control.

HARBOR PROJECTS IN CHICAGO DISTRICT

project is only in its preliminary stages but that there is no adequate accommodation for such vessels as are expected to reach Lake Michigan if, and when, this waterway is completed. On the other hand, it is planned to have the Illinois link in the Lake and Gulf waterway completed in five years, but this will be for barge traffic and not for large steamers. Closing the Chicago River to all navigation is not approved, since the commission considers a local harbor desirable at the mouth of the river, with barge service to industries along the river. Further, barge navigation in connection with the Lake and Gulf waterway "can be provided through the Chicago River cheaper than through the Calumet River." Under this plan drawbridges would not be needed.

As a result of its study the commission has made the following recommendations and states that the proposed developments together with existing facilities will serve for many years:

1. Development of facilities along the mouth of the Chicago River to serve the city's commercial district.
2. Development of harbor facilities along both branches of the Chicago River for barge transportation in connection with the Lakes and Gulf waterway.
3. Development of the harbor facilities of the Calumet River for industrial purposes.
4. Improvement and development of Calumet Lake as an industrial and transfer harbor, having adequate connections with Lake Michigan and the Calumet-Sag canal.

Tall Unbraced Timber Posts Cause Falsework Failure

Built-Up Columns, Made of Five Thicknesses of 2 x 10-In. Planks, Buckle When Concrete Pouring Is Under Way

FAILURE of falsework due to the buckling of unbraced, built-up timber posts in a bent carrying one end of truss supports for the deck and girder forms of a concrete road bridge span was recently the cause of a serious accident in building an eight-span bridge across the Haw River in North Carolina. A 50-ft. span being concreted fell into the river carrying with it and injuring several workmen. Investigation disclosed that the contractor had used 30-ft. posts in the bents supporting the trusses, had built the posts of short

planks spiked together and had used no bracing between posts. The sketches indicate where it failed.

As stated, the bridge had eight spans. All were 50-ft. deck-girder spans with a 20-ft. roadway and two 5-ft. sidewalks. The spans were reinforced and so were the abutments, but the simple slab piers, indicated by the view, were plain concrete. I-beams trussed as shown carried the deck forms and were braced together across the span by 2x6-in. planks. The ends of the trusses rested on the caps of timber bents set close against the piers and on the pier footings. In the span

which failed the posts of the bents were approximately 30 ft. long and were made up of five thicknesses of 2x10-in. plank spiked together. The planks composing the posts were less than full length but they had been spiked with staggered joints. The posts were set with the 10-in. sides of the planks parallel with the length of the span. Originally there was, between cap and sill, no bracing between posts.

Buckling of the composite columns was first noticed after about 25 cu.yd. of concrete had been poured. The two outer columns of a bent buckled outward about 2 ft. causing a settlement of some 3 in. in the outside trusses. Work was stopped and the forms were brought back to line by adjusting the wedges. Also the posts were braced by spiking to them 2x10-in. plank diagonals. Pouring concrete was resumed but after about 75 cu.yd. were in place additional buckling was noticed and within a short time the entire falsework collapsed. It was evident that the buckling of the two outer posts caused a downward deflection of the cap which threw the outer trusses out of plumb thus bringing an eccentric load on them which caused failure. The remaining trusses were carried along in the collapse by the horizontal bracing connecting the trusses.

Standard Signs for Mississippi Valley State Roads

ADoption of standard caution and guide signs and other safety devices on highways in the Middle West States has been recommended by the Mississippi Valley Association of State Highway Officials. The Minnesota Highway Department states that it will follow the recommendations as closely as possible, particularly that portion with reference to shape. Old signs are not to be destroyed but when new ones are erected they shall conform.

Some of the recommendations are as follows: Route marks are to include road numbers and be of the distinguishing symbol characteristic of each state. All warning signs shall be uniform in all states and guide and information signs as uniform as possible. Warning and guide signs are to be black and white. Warning signs are not to be placed at too frequent intervals because the public then discredits their value. The location is to be 3 and 4 ft. above the center of the road, 1 ft. outside of the outer shoulder line and 300 to 500 ft. back from the danger point. Round signs 2 ft. in diameter indicate railroad crossings; octagonal, 2 ft. across, stop; diamond, 2 ft. square, slow, and square, 2 ft. caution. The stop sign should be located in the center of the road. Guide signs are to be rectangular and of suitable size to accommodate the information. Advertising signs on right-of-way or pavement are forbidden.

BUCKLED POSTS OF FALSEWORK BENT

Predicting Next Year's Rainfall for Southern California

Scientists Attempt Basis for Long-Range Seasonal Forecasts by Study of Ocean Currents and Atmospheric Pressures

BY PAUL A. EWING
Oakland, Calif.

Table copied and text rewritten from official publication of San Diego County Farm Bureau.

URGED by the constantly growing seriousness of the water scarcity, scientists in Southern California have finally evolved a system of long-range rainfall forecasting which promises eventually to establish a basis for anticipating, with a fair degree of certainty, seasonal precipitation for the California coastal region or for any other section whose climate is similarly affected by ocean currents and the distribution of atmospheric pressures. Particular attention has been directed to the possibility of seasonal forecasts by western meteorologists for many years past, the need for such anticipatory knowledge being of great importance there on account of the rapid expansion of irrigation and power developments having a close dependence on rainfall. The influence of sun-spots has been much discussed, and even the growth of rings of trees has been studied to obtain seasonal variations of weather. The close relation of weather to barometric pressures has been the basis of the studies conducted by Scripps Institution of Biological Research, at La Jolla, Calif., and it is upon the accumulating results of these observations that present hopes of California agriculturists and hydro-electricians are centering.

While the scientists of Scripps Institution who have had this work in hand are not yet willing to assert that dependence may be placed upon forecasts based on their records, on account of the comparatively short period covered; they have been much encouraged by successful forecasts of the monsoon rainfall of India, months in advance, which were based upon observations of atmospheric pressure distributions over vast areas of land and water. Prof. George F. McEwen, in charge of the forecasting studies at La Jolla, has now a six-years' record of ocean temperatures for a ten-weeks' period each year, and the seasonal rainfall observed at six inland recording stations following the date to which the summer temperature corresponds. The computed rainfall and that actually observed during the six years recorded are in no case far apart.

Recording Stations—Six stations were selected in two groups of three each, Bonita, San Diego and Escondido representing the coastal region of San Diego County, and Tustin, Corona and Los Angeles being assumed to be representative of the northern part of Southern California. The average rainfall of all six stations was considered as representing the general coastal region of Southern California. In tabulating the data secured so far and computing the values of the seasonal rainfall from temperature observations, it was assumed that the departure of the temperature at any season from the average during the period of observations is proportional to the departure of the subsequent seasonal rainfall from its average value. The temperature departure multiplied by the constant factor 2.4 gives the computed rainfall departure. This is shown in the accompanying table, prepared by Prof. McEwen.

As explained by Prof. McEwen, the general atmospheric circulation between equatorial and polar regions brings about the high barometric pressure in the belt centered near the parallel of 35° N, the lower air of the equatorial region forming the west-bound trade winds, and that north of the parallel forming the westerlies. The deflecting force of the earth's rotation, acting to the right, forces the two oppositely-flowing currents of wind together, compressing the air between, and so forming the high-pressure belt; and the smooth surface of the ocean permits a higher wind

velocity than does the land, so that the barometric pressure is greatest at sea. To all this is added the thermal effect due to the difference in radiation and evaporation from the land and water surfaces, which makes the land in the high-pressure belt colder than the water in winter and warmer in summer. In the latter season thermal dynamic causes together develop and maintain the belt of high pressure, but with the approach of winter the air flows landward in response to changing temperature relations. By mid-winter the dynamic causes have the upper hand and a land "high" is developed by the transfer of a great mass of air from the ocean to the continent. The fact that the probable amount of this air movement could be estimated if detailed measurements of the pressure distribution over the North Pacific were available was what suggested the possibility of forecasting the consequent seasonal rainfall from pressure observations made during the summer.

Theory Stated—The practical impossibility of securing such observations in sufficient number would have prevented use of the idea; but the known relationship between pressures and surface ocean temperatures off the coast of California still permitted the study to proceed. Briefly, the theory is that the lower the surface ocean temperature, the greater the intensity of the ocean "high" and the heavier the consequent seasonal coastal rainfall. The results of

Year	Ocean Temp at Institution Pier for Ten Weeks Aug. 1 to Oct. 15, Deg. F.*	Seasonal Rainfall† Following Date to which the Summer Temperature Corresponds.*					Computed Departure From 6-Year Seasonal Mean
		Bonita San Diego	Escondido	Tustin Corona	Los Angeles	Mean of All Six Stations

1922-23.....	67.8						-0.5

* First of each pair of columns gives actual figure for the period indicated, while second column of the pair gives departure from 6-yr. mean.

† The seasonal rainfall is for the year beginning July 1 of the year at the extreme left.

daily surface temperature observations at Institution Pier, La Jolla, agree with this inferred correlation between temperature and rainfall, showing that a fall of one degree in temperature corresponds approximately with an increase of about 2 in. in the subsequent seasonal rainfall. Prof. McEwen refers to the results obtained so far as "the first crude approximation to the lengthy and detailed investigation that should be made." The studies are being continued and extended, with the idea that a long record may eventually permit accurate predictions of the rainfall many months in advance, to the very considerable benefit of agricultural and industrial interests of the southern part of California.

Self-Contained Steam Railway Coaches

A new type of self-contained, steam-driven railway coach has been developed for use on British railways. The coach is known as the Sentinel steam railway coach and is capable of developing a speed up to 50 m.p.h. It is remarkable in that while the average weight of the present steam railway coaches is over 40 tons, or about 1,650 lb. per passenger carried, the new coach as designed for standard-gauge railway weighs less than 500 lb. per passenger carried. Similarly, the fuel consumption of the heavy type of coaches is approximately 25 lb. of coal as against 4 lb. per mile for the new Sentinel car, and the water consumption is 15 gal. as against 2½ gal. per mile. The boiler of the Sentinel coach is designed to operate with either coal, coke, charcoal, wood, or waste vegetable products, and therefore is capable of being operated in almost any locality. The light weight of the car makes it possible to operate it over railways that on account of light track or bridges are incapable of carrying the heavy railway coaches.

Ice House Wrecked by Overturning Ice Due to Flood

BY CHARLES W. LUSK
City Engineer, Arkansas City, Kan.

ON JUNE 10 flood waters of the Arkansas River descended upon Arkansas City, Kan., setting a new high-water mark 8 ft. above all previous levels. More than a third of the residential section of the town and part of the business section were covered with water 2 to 15 ft. deep. Thousands were driven from their homes, and the property loss has been estimated in the millions. In this flood a new ice storage house was wrecked in remarkable manner; it constitutes one of the largest single losses.

Last year the Arkansas City Ice and Cold Storage Co. completed construction of one of the most modern ice manufacturing plants in the middle west, which supplies

CONCRETE ICE HOUSE WRECKED
Flood waters melted lower layers of ice causing pile to overturn.

ice for refrigerator cars on the A. T. & S. F. Ry. from Kansas City to Fort Worth. This 10,000-ton season storage house was valued at \$165,000. It was practically demolished by the melting and overturning of the pile of 40,000 300-lb. cakes of ice stored in it.

The building, which is 50 x 100 ft. in plan, rests on a foundation 4 x 4 ft. running entirely around the four walls. The floor is a 3-ft. cinder fill on the ground surface, with 10 x 14-in. timber stringers and 2 x 10-in. timber flooring. The walls are 9-in. reinforced-concrete slabs 50 ft. high, with 2-ft. square pilasters 16 ft. on centers, and 2-ft. square reinforced belt courses at the base, the middle height and the top. The walls inside the concrete slabs consisted of a 13-in. space filled with mill shavings, and twolayers of 1 x 8 -in. shiplap siding with tarred paper lining. The roof was constructed of steel girders 16 ft. on centers, 2 x 10-in. timber stringers, two courses of 1 x 12-in. sheathing with paper lining, and three layers of 2-in. cork insulation laid in asphalt, covered with three-ply asphalt roofing. From the roof were suspended four series of cooling coils containing 22,000 ft. of 2-in. wrought pipe.

At the time of the flood the storage house contained some 6,000 tons of season storage ice, piled regularly with about 4 ft. clearance around all walls. The flood waters, rising 7 to 8 ft. above the floor level of the building, filtered in through the door openings and partially melted the lower tiers of ice cakes. The entire mass of ice tipped against the east longitudinal wall and forced it outward, permitting the roof to sag to the ice pile.

The foundations, parts of three walls and the floor are still intact, but the roof, the cooling system and one wall are completely wrecked. Except for 200 tons salvaged, the 6,000 tons of ice, valued at \$36,000, were lost.

The company has other storage of 1,000 tons capacity that was not damaged by the flood, and by July will be turning out ice at the rate of 120 tons daily, so that all demands will easily be met. Rebuilding of the damaged storage house will be started late this year.

British Experiments With Rubber Paving

London Correspondence

RUBBER in several forms is being tested for street pavement in London, England. In one instance the rubber was laid in a business thoroughfare, carrying a traffic of 240 tons per yard width per hour. The section paved varies from three to five yards in width between the curb and tramway margin on one side of the road only, and is fairly level. Two types were laid: (1) 9x3x1-in. rubber, vulcanized on expanded metal and anchored to concrete. The area laid was 161 super yards. This has had two years' wear. (2) 8x4x4-in. composite blocks laid on concrete foundation, similar to wood blocks; area laid, 20 sq.yd. This has had one or two months' wear.

This work was carried out in December, 1920, and January, 1923. The foundation consists of 6-in. to 9-in. reinforced concrete, and the price of the paving (including cost of foundation and estimated cost of rubber blocks) is about £5 per sq.yd. The rubber was supplied free to the council, who laid the paving with direct labor. The engineer states that in his opinion rubber has proved to be a most suitable material for road paving, showing a minimum of wear. Possibly the second type (the composite blocks) may prove to be the ideal form of using rubber for paving purposes.

In another instance experimental rubber paving blocks were laid at the exits of a dock. The paving blocks in this case were 9 in. long, 3 in. wide and 3½ in. deep and consist of hard basic compound with approximately ¾ in. of rubber capping directly vulcanized on the 3-in. width of face. A test piece of roadway of 50 sq.yd. (30x15 ft.) consisting of these blocks on a foundation of 6 in. of cement concrete was laid. The approximate tonnage of loaded vehicles such as motor trucks and wagons (excluding passenger and unloaded vehicles) passing over or brought to rest on the test piece has been on an average 18,000 to 20,000 tons per month. The average total tonnage, however, of loaded and unloaded vehicles traversing this test area would approximate to some 30,000 tons per month.

A close examination has disclosed no signs of wear in the rubber capping surface, and only in two places can any signs of movement be detected; in both these cases a course of the blocks crept forward to a trifling extent, which may probably be attributed to a slight movement in the granite curbs placed at each end of the test portion to enclose the area.

The surface shows no signs of slipping or skidding, which is surprising in view of the fact that the test portion is subjected to fast and slow moving traffic in addition to heavily-laden trucks and wagons pulling up on it and restarting, since, as mentioned before, it is laid outside one of the busiest box offices on the dock premises where the main cargo traffic has to stop while documents are being dealt with.

A New Transmission Line Tested by Frozen Fog

Warm Moist Air Rising Into Cold Mountain Regions
Encases Transmission Line with Ice—
Will Be Insulation Problem

By WILLIAM D. SHANNON

Superintendent of Construction, Stone & Webster, Inc.,
San Francisco, Calif.

THE 110,000-volt transmission line to carry power from the White River hydro-electric station to the apple district of the Wenatchee Valley in the State of Washington has the unique distinction of passing through five counties, each county showing a special peculiarity of climate. The route that this line follows passes over two ranges of mountains and partially traverses three valleys, thus giving five physical conditions running the whole gamut of weather varieties and ranging from the mild climate of the Puget Sound region, with its high humidity, to the cold dry climate of the Wenatchee Valley.

In one instance there is a conflict between two climatic conditions, which during the first winter of operation produced an interesting phenomenon. This condition

ONE OF THE TOWERS AFTER THAWING HAD STARTED

was found at the boundary line of two counties, which happens to be at the summit of the Cascade Mountains. The elevation at this point is 3,900 ft. above sea level and the mountains are therefore covered with snow during the winter season. At certain times during the winter, the moisture-laden winds from the Puget Sound area blow eastward up the Green River Canyon, keeping at a comparatively low elevation until within two miles of the summit. The rise over the summit is therefore rapid to the point where the winds meet the dry cold air currents from the Kittitas Valley. In its rapid ascent up the slopes of the mountain range, the moisture laden air partially condenses until it becomes a heavy fog. On the last 500 ft. of ascent the fog rapidly congeals and at the summit is of such form that it adheres instantly to anything it touches. At this stage of its transformation, the fog undergoes a small physical change, so that it may be aptly described as "frozen fog" or as one of the engineers described it "fog frango." The accumulation or growth of this "frozen fog" is very rapid and in a few hours' time a steel tower may become coated with one or two feet of the "frango." The accompanying photographs were taken after thawing had started. From all indications, the masses of "frango" on the towers, insulators and conductors must have been enormous, and it is reasonable

ICE FORMATION AT THE TOP OF A TOWER

to suppose that the whole mass of structural steel was as heavily coated as was the top. One photograph shows the top of the tower after all the "frango" on the lower portion had melted away. The top was practically an entire mass of ice.

A windrow of ice and snow on the ground under each wire was mute evidence of the punishment the copper conductor received during the "fog storm." The size of wire in this district was 4/0 H.D. stranded copper. While none of the "frozen fog" was weighed a conservative estimate would be not over 10 lb. per cu. ft.

A recent number of the *National Geographic Magazine* contained a photograph of a similar phenomenon on the summit of Mount Washington in New England.

This transmission line was not in operation at the time this storm occurred. It is being constructed for the Puget Sound Power & Light Co. by the construction and engineering division of Stone & Webster, Inc.

Strain-Gage Used to Check Bridge Reinforcement

In strengthening an old four-span bridge on the Great Northern Ry. by the addition of a center truss, recently, strain-gage measurements were made on the completed structure to verify the assumption made in designing the reinforcement that the three trusses would divide the load in proportion to their respective strengths. H. S. Loeffler, assistant engineer, describing the operation in the *Railway Age* of May 12, states that strain-gages were attached to similar members of the three trusses of a span and the maximum reading of each instrument during the passage of a train was noted. In every test it was found that stresses occurring simultaneously in similar members of the three trusses in any span were practically identical. The bridge crosses the Mississippi River at St. Cloud, Minn., and consists of pin-connected steel truss deck spans, 170 ft. long, built in 1893 on old masonry, and designed for a capacity equivalent to Cooper's E 33. The center truss applied to each span is also pin connected, and is of the same depth as the old trusses, but is placed lower by 6 ft. 3½ in. to bring its top chord under the floorbeams. It was designed to carry E 30 loading, so that the bridge now is good for E 63. Stiff swaybracing has been inserted. Three other bridges are to be reinforced in similar manner this year: A 160-ft. deck span at Sandstone, Minn., two 215-ft. deck spans at Coram, Mont., and a viaduct at Minot, N. D. A. H. Hogeland is chief engineer and J. A. Bohland is bridge engineer of the Great Northern.

Building a Concrete Flume in Rough Country

Railroad Built Along Line From Source of Materials and Then Taken Up as Flume Is Built in Reverse Direction

By H. K. Fox

Construction Superintendent, San Joaquin Light & Power Corporation, Fresno, Calif.

A CONDUIT and flume line, $2\frac{1}{2}$ miles long, was recently completed by the San Joaquin Light & Power Corp. on the north fork of the San Joaquin River in California, by means of which the water supply serving a chain of six power houses will be materially increased. The inaccessibility of the upper end of the conduit line and the fact that a grade for a flume was cut along approximately the same location in 1910 made it advisable first to build a construction railroad along this old line, beginning at the lower end which was reached by

upper side where possible. Where the line crossed ravines, trestles, to be used later by the steel flume, were built first and the railroad was carried across on them. The trestles were built as the railroad advanced so that except for a small amount of cement used in the trestle footing no material had to be carried in on the backs of workmen.

As soon as the track reached the intake, construction of the small concrete arch dam was immediately started just above the old rock crib diversion. This new diversion dam is about 30 ft. long, 2 ft. thick throughout and 10 ft. in height, with reinforcing in both faces. A very simple form of inlet gate made of redwood was used. Thus a source of water supply and inlet control at the flume head was provided before construction of the conduit itself was started.

The material handling plant was small and simple. A quarry was opened on the right-of-way and a 9x18-in. jaw crusher set up over a 40-cu.yd. storage bin. The

FIG. 1—FORMS AND REINFORCING IN PLACE

FIG. 2—COMPLETED CONCRETE FLUME

road, and then to build the new conduit from the upper end down. With this plan a constantly advancing source of water supply was made available by admitting water from the upper end to completed sections of the conduit. The entire job was finished in eight months with one daily 9-hour shift.

The original conduit built in 1910 to provide sluicing water for the Crane Valley Dam was a combination unlined ditch and wooden box flume with a capacity of 30 sec.-ft. The flume and trestles were largely destroyed by forest fire. The new conduit line consists of concrete lined ditch, concrete box flume, and riveted steel flume on redwood trestles, all with a uniform capacity of 100 sec.-ft. Very careful figuring was required to make the new construction fit the old grade and at the same time conform to uniform cross-sections as far as possible. It was not advisable to change the section more often than absolutely necessary, due to the additional cost and delays which such changes made in forms and reinforcing.

A construction headquarters was first established at the lower end of the line and a small warehouse and material yard were built there. An 18-in. gage railroad with 12-lb. rails was then constructed. Most of the ties were salvaged from what was left of the old flume and the track was laid alongside the old ditch, on the

crusher jaws were set to produce rock with a maximum size of $\frac{3}{4}$ in. and because of this close setting produced a greater portion of the sand than would otherwise have been obtained. The product was not screened, crusher run being used by adding some sand. A spur from the track allowed dump cars to run under the chutes of the bin. Three 1-cu.yd. cars were handled in a train by homemade locomotives consisting of a Ford engine mounted on a steel frame with a special transmission to chain sprockets on all four wheels.

These locomotives proved very successful. There were several short stretches in the track which had grades as high as 14 per cent and on these the locomotives would haul 120 sacks of cement. The usual requirements of the locomotives under these operating conditions were 7 gal. of gasoline and 1 quart of oil for nine hours service.

The mixer was a gasoline-driven, one-sack batch machine specially mounted on flanged wheels. Six successive setups were used at advantageous points on the line. At each of these points the mixer was placed on a spur where it could discharge into cars on the main track. For the ditch lining the concrete was discharged directly from the cars into the ditch and for filling the forms for the box flume into concrete buggies which traveled on a plank runway laid on top of the forms.

FIG. 3—TYPICAL FLUME SECTION WITH STANDARD REINFORCING

This section has the following hydraulic values: grade, 1 in 675; velocity, 5.54 ft. per second; flow, 100 sec.-ft.; value of N in Kutter's formula, 0.014.

Thus the advantage of having the track above the conduit is apparent. The only available water supply was that retained in the flume itself by sack dams built across completed sections of the flume as near the work as possible. A gasoline-driven pump delivering into a 2-in. pipe line to the mixer and ditch-shaping crew was installed with its intake just behind the sack dam. One day was required to move the dam and pumping equipment forward as work progressed.

The old ditch section was enlarged to carry 100 sec.-ft. and before placing the concrete the earth was well soaked to avoid settling away from the lining. The maximum progress for the concreting crew of 10 men per 9-hour day was 360 lin.ft. A fairly dry concrete was used, the floor being poured first and the sides on the day following. No difficulty was experienced in placing the concrete on the slope, the method being simply to throw it on with shovels to the depth of the squeeds, and smooth it up with wood floats following with steel floats for the finish; no skilled labor was used. The best progress on the sides alone was 385 ft. per day.

The concrete box flume was designed without expansion joints, sufficient steel being provided so that nothing but hair cracks is expected as the result of temperature changes. To date practically no visible cracks have developed. The reinforcing was varied to give the flume box additional strength where the floor was not fully supported or where there was considerable external earth pressure.

Type 1 reinforcing, illustrated in the accompanying cross-section, was standard, and to this was added more steel as specified in types 2 and 3 (not illustrated) which were designed to meet the two special cases mentioned where additional strength was required.

FIG. 4—FORD LOCOMOTIVE WITH TRAINLOAD OF 120 SACKS OF CEMENT

The forms were the key to the rapid progress made in constructing the box section. They were designed with practical considerations paramount and no changes were found necessary as the work proceeded. The panels, made of 1-in. ship-lap, were all 3 ft. long and 3 1/2 ft. high, no specials being used on curves. To make curves with forms of standard length, wall forms for the longer or outer side of the curves were supplemented by strips or "Dutchmen" of varying width placed between the ends of the panels.

The process of setting up forms and pouring concrete was programmed as follows: (1) the 2x6-in. sills were carefully set to line and grade, (2) floor reinforcing placed, (3) outside panels with cross-ties on top set in place, (4) side reinforcing, (5) inside panels, and, finally, (6) cross bracing.

The wall forms were held in place at the top by the 2x8-in. cross-ties bolted to the panel studs. At the bottom the outside panels were prevented from spreading by No. 10 wires laid across the sills in pairs and

FIG. 5—PLACING CONCRETE IN LINED DITCH

twisted up, after the panels were placed, around the bottoms of the panel studs. These wires extended the full width of the flume box from outside to outside. The panels were fastened to one another, at the outset, by hook bolts. Nailing blocks were soon substituted as being much faster and better suited to the use of "Dutchmen" on the curves.

The maximum progress for a crew of six men in setting up the forms complete was 200 ft. per day. The maximum progress in pouring was about 238 ft. per day. The floor was ordinarily kept poured about 20 ft. ahead of the sides.

Concrete was delivered from the mixer in side-dump cars, a maximum distance of 2,000 ft., but because of the danger of taking initial set en route it was not found advisable except in unusual cases to deliver distances greater than 1,000 ft. from the mixer.

The work was done by the San Joaquin Light & Power Corp. under the direction of R. C. Starr with the writer as superintendent of construction and A. M. Smith as resident engineer.

New Specifications and Facts Concerning Materials

Twenty-sixth Meeting of American Society for Testing Materials Shows Steady Extension of Committee Work—Society to Cultivate Research in Materials—Behavior of Concrete Under Discussion

CONTINUED broadening of the scope of its specification work was apparent at the meeting of the American Society for Testing Materials at Atlantic City last week. The organization entered its second twenty-five-year period of existence with the novel condition of having relatively little specification work to report in the field of the major materials—steel, cement and wood—but a great deal in miscellaneous materials and items, from broken slag and rubber matting to thermometers. There was rather more than the usual number of technical papers, in line with the deliberate effort of the past few years to develop this side of the society's work more fully. New results of the study of materials and various interesting new instruments were described. Several special subjects were discussed at considerable length, one of them being the group of phenomena and terms described by such words as consistency, plasticity, workability, and the like, and another being the condition of concrete structures, with special reference to the defects which they have developed in service. This latter discussion, despite the unfavorable condition of being placed in the closing session—the thirteenth—of an excessively long and fatiguing meeting occupying an entire week, was in certain respects its most important and most sensational feature.

With nearly 900 members in attendance, the meeting far surpassed previous ones in point of size, and represents an increase well beyond the increase in total membership.

To Develop Research—Carrying out a suggestion made in the presidential address of J. A. Capp several years ago, the society has now decided to enter upon a systematic effort to stimulate and cultivate research in its work and its meetings.

Special emphasis was laid on the importance of research in the address of the retiring president, Dr. George K. Burgess, director of the Bureau of Standards, which had the general subject "The Trend of Standardization." The main portion of the address was a strong exposition of the value of standard specifications and a denial of the charge that has sometimes been made that standardization will interfere with the freedom of development of the arts.

A matter also dealt with in the address, and one which is assuming renewed and serious importance in the society's work, is the difficulty of obtaining proper balance between producer and consumer in the formulation of specifications. The charge often heard in former years that the specifications of the society are essentially manufacturers' specifications is again coming to the front, and has received serious consideration in the councils of the society. President Burgess referred to "the importance of maintaining adequate attendance of representatives of consumers' interests at committee meetings to secure at all times a real balance of producer and consumer in the formulation of standards and specifications."

Talbot Made Honorary Member—Past president Arthur N. Talbot was elected to honorary membership in the society, in recognition of his long, brilliant

career in the study of materials and the testing of structures, carried on mainly at the University of Illinois.

Guilliaem Aertsen, of the Midvale Steel & Ordnance Co., was elected president of the society to succeed Dr. Burgess. W. H. Fulweiler, of the United Gas Improvement Co., is the new vice-president, and the following four become members of the executive committee: J. H. Chubb, of the Universal Portland Cement Co., T. G. Delbridge, of the Atlantic Refining Co., H. L. Scott, of Henry L. Scott & Co., and P. H. Walker, of the U. S. Bureau of Standards.

In the general field of the society's committee work the meeting showed that important work is being done in two new fields entered within the last year or two, namely, the unification of nomenclature in the field covered by the society, and the harmonizing and standardizing of test methods. On the latter subject, the committee on methods of testing presented an outline specification for tension tests of metals. However, it also proposed to change the current definitions of stress and strain by defining stress as the intensity of internal force in a piece in pounds per square inch, and strain as the deformation per inch of length. There was much opposition to this radical proposal, but by rather routine vote it was approved by the meeting for tentative publication. The committee has laid out an extensive program of work, with the ultimate purpose of placing all test procedure on a standard basis, and its work so far is only a beginning.

Progress in Specifications—While most of the specification committees of the society work independently rather than in conjunction with other societies, the reports of the past year's work presented at the meeting indicate that there is steady improvement in the general tie-up the committees with other organizations. Contact secured in this way led to the revision of several specifications during the past year, including those for trolley wire, in which field there is a close tie-up with the work of the American Electric Railway Engineering Association. Direct co-operative work was not noticeably extended during the past year.

The broad range of the specification work and its highly detailed and specialized character in most instances make it impracticable to review this work here. The new specifications presented at the meeting, all of which were approved by the meeting for publication as tentative, are listed below.

Steel

Boiler and fire-box steel for stationary service
Steel plates of flange quality for forge welding

Copper Wire

Hard drawn copper trolley wire
Soft rectangular copper wire
Hot-rolled copper rods for wire drawing

Corrosion of Iron and Steel

Method of determining weight of coating on zinc-coated articles
Method of determining weight of coating on tin, terne and lead coated sheets

Wire Cloth

Non-ferrous screen wire cloth

Metallography

Definitions of terms relating to metallography
Recommended practice for photography as applied to metallography

Methods of metallographic testing of non-ferrous metals and alloys

Timber

Test for coke residue of creosote oil

Methods of Testing

Methods of tension testing of metallic materials
Definitions of terms relating to methods of testing
Methods for verification of testing machines

Road and Paving Materials

Method of test for the determination of proportion of bitumen insoluble in carbon tetrachloride

Asphalt cement, 25 to 30 penetration, for use in sheet asphalt and asphaltic concrete

Asphalt cement, 30 to 40 penetration, for use in sheet asphalt and asphaltic concrete

Natural or artificial sand-clay mixtures for road surfacing

Broken slag for bituminous macadam wearing course

Broken slag for bituminous concrete (coarse-graded aggregate type)

Broken slag for bituminous concrete (fine-graded aggregate type)

Sand for sheet asphalt and bituminous concrete pavements

Lime

Method for measurement of consistency of lime pastes

Gypsum

Gypsum partition tile or block

Coal and Coke

Method of test for volume of cell space of lump coke

Gas and coking coal

Paint and Varnish

Definitions for toughness and elasticity

Tests for specific gravity or pigments

Methods for testing shellac

Methods of testing oleoresinous varnishes

Waterproofing Materials

Asphalt mastic for use in waterproofing

Bituminous grout for use in waterproofing above ground level

Bituminous grout for use in waterproofing below ground level

Felted fabric saturated with bituminous substances for use in waterproofing

Woven cotton fabric saturated with bituminous substances for use in waterproofing

Burlap saturated with bituminous substances for use in waterproofing

Petroleum Products

Method of test for water in petroleum products and other bituminous materials

Method of test for color of lubricating oil by means of Union colorimeter

Method of test for color of refined petroleum oil by means of Saybolt chromometer

Method of test for steam emulsion of lubricating oils

Method of testing gas oils

Electrical Insulating Material

Method of test of electrical insulating materials for voltage effects at radio frequencies

Method of testing cable splicing and pothead compounds

Rubber Products

Wrapped cold water hose

Rubber matting for use around electrical apparatus or circuits not exceeding 3,000 volts to ground

Textile Materials

Imperfections and tolerances for cord tire fabrics

Tolerances and test methods for cotton yarns and cords

Tolerances for hose ducks and belt ducks

Thermometers

Thermometers (four classes)

Following long established custom in the society, the committees reported these specifications as well as numerous detailed revisions of existing specifications

without indicating reasons or essential elements. In consequence the proceedings in the meeting, so far as they related to the committee work, were formal and devoid of any special interest. Quite recently, however, the executive committee decided to change this practice by calling for statement of reasons in connection with the revision and formulation of standards in future.

Phosphorus and Sulphur Investigation—A second report of the joint committee on investigation of phosphorous and sulphur in steel was presented, in preliminary form. While the definite data are not yet ready for publication it was stated that in plate steel, with sulphur ranging up to 0.15 per cent, the results are substantially the same as previously reported for rivet steel, showing no influence of sulphur variation upon the several strength properties of the material, except that the Charpy impact values are erratic.

Corrosion Test Results—Further report was made on the elaborate exposure tests of bare iron and steel sheets conducted by the committee on corrosion of iron and steel. Atmospheric exposure tests at Pittsburgh, at Fort Sheridan (Ill.), and Annapolis confirm the previously indicated conclusion that steel containing copper is much more resistant to corrosion than steel free from copper. Three other sets of tests, with the samples immersed in water, have not yet led to definite conclusions, but up to the present show that copper-containing steel has no advantage over copper-free steel in water immersion. As the tests have developed up to the present, the acid mine water at Calumet, Pa., has six or seven times as rapid a corrosive effect as city water in Washington, and the latter has several times as strong an effect as brackish water at Annapolis.

New Instruments—Two remarkable extensometers were described, both having been developed during the past year at the Bureau of Standards. O. S. Peters and R. S. Johnston, under the title "New Developments in Electric Telemeters" described the carbon resistance extensometer which has already found useful application in the test of wide web plates made for the Delaware River Bridge Commission. L. B. Tuckerman, in a paper on "Optical Strain Gages and Extensometers," described a mirror extensometer with ingenious triple-reflection optical lever and an autocollimator reading telescope, which with the triple mirror eliminates disturbance and errors due to shift of the telescope, and has a very high sensitivity, reading easily to 0.00001 in. in displacement. Another ingenious instrument was described by E. B. Smith, of the U. S. Bureau of Public Roads, under the title "An Accelerometer for Measuring Impact." In this device a small hammer moving against a spring and automatically held in the position of its extreme throw measures the force of negative acceleration. It is available for truck-wheel impact and pile-driver work and the like.

A wear machine developed in the Goodrich laboratory to measure the abrasive resistance of rubber compounds was described by W. W. Evans. G. B. Haven presented "A Constant Load Rate Testing Machine for Textiles." In this instrument the load is applied by a weight resting on an inclined plane, and changing the inclination of the plane changes the load in uniform increments. A device by which the color of oils may be compared more effectively than heretofore was described by D. C. Cox, under the title "A Method for the Estimation of Color in Oils." The instrument com-

compares the amounts of blue light absorbed by two oils, these amounts taken to be a measure of the yellow or red color of the oil.

Chemical Limits for Cast Iron—In a topical discussion on the subject "Is It Desirable to Include Chemical Requirements in Specifications for Cast Iron?", Robert Job upheld the view that good results cannot be obtained, in many classes of cast-iron service, without careful specification of the limit of various elements, such as sulphur, combined carbon, and the like, while Richard Moldenke urged that the foundryman be left free to meet the required physical properties by any chemistry that he finds suitable. However, Mr. Moldenke admitted the need for fixing chemical limits in certain cases, and the general result of the discussion was to support strongly the modern tendency toward fixing chemical requirements for cast iron almost as definitely and fully as for steel. H. J. Force, in particular, made a strong presentation of the case for chemical specifications in car wheels and locomotive cylinders.

Magnetic Analysis—An elaborate study of magnetic analysis in application to twist drills was reported by the committee on magnetic analysis. Some fifty or sixty drills especially made for the purpose were tried as to their cutting properties and their magnetic properties, and in general no correlation was found. In connection with the same work, however, A. V. deForest developed an instrument in which two independent magnetic measurements are taken on the sample, the claim being made that under proper manipulation the magnetic measurements indicate respectively the quenching temperature and the drawing temperature of the specimen, thereby in turn indicating the cutting power. Some success was attained in applying this instrument to the drills, suggesting the need for further study.

Paint Studies—H. A. Nelson and G. W. Rundle gave results of elongation measurements on paint films, and the effect of moisture on the elongation. No direct conclusions followed.

Two papers on the relation between white paint pigments and ultra-violet light demonstrated convincingly that certain pigments reflect more ultra-violet light than do other pigments, but opposite conclusions were drawn, one showing the advantage of zinc oxide, the other the advantage of white lead. Discussion of the two papers merely continued the general antagonism of the zinc and lead interests that has been displayed in previous paint sessions of the society.

Preservative Value of High-Test Creosote—A final report on a fungus-bed test of wood preservatives was presented by Cloyd M. Chapman, covering some 30 different preservatives and several kinds of wood. The results indicate that high-boiling creosotes are the best preservatives, but that no preservative and no method of treatment tried will furnish complete protection from active decay attack. An abstract is given on p. 27 of this issue.

New Facts on Fatigue of Metals—Elaborate further data on the fatigue of steel were presented by D. J. McAdam, Jr., of the Naval Engineering Experiment Station, while R. R. Moore of the Army Air Service reported on extensive fatigue tests of manganese bronze, duralumin and electron metal. These papers made important additions to the knowledge developed by

the fatigue research carried out at the University of Illinois under the auspices of the National Research Council. An abstract of the results of one of the papers is given on p. 26 of this issue.

Of the other papers presented, the following may be noted: "Methods of Casting Test Specimens of Gun Metal," by E. H. Dix, Jr.; "The Influence of the Ratio of Length to Diameter in the Compression Testing of Babbitt Metal," by John R. Freeman, Jr., and Paul F. Brandt; "The Properties of Metallurgical Coke," by G. S. Perrott and A. C. Fieldner; "The Significance of Tool Temperatures as a Function of the Cutting Resistance of Metal," by H. A. Schwartz and W. W. Flagle; "Gases in Metals," by Louis Jordan; "The Testing of Glue," a discussion led by Jerome Alexander; "Some Relations Between the Characteristics of Straight Distilled Tar Residues," by J. W. Kennedy; "Use of an Air Bath in Determination of Solid Residue of Road Oils at 100 Penetration," by H. F. Clemmer and H. C. Helmle; an elaborate scientific dissertation under the title of "Color," by G. W. Thompson; "A New Combined Viscometer and Plastometer," by E. C. Bingham and H. A. Perry, Jr.; and several papers on insulating varnishes and on slate.

What is Consistency?—The best part of one session was devoted to the discussion of the principles underlying the measurement of consistency, plasticity and related properties, particularly as such discussion might lead to a definition of consistency. It was introduced by F. G. Breyer and Henry Green, of the New Jersey Zinc Co., who define consistency as "that property of a plastic material which it possesses by virtue of its yield value and mobility, and manifests itself as resistance to flow." W. E. Emley, of the lime committee said since lime which can maintain its consistency long enough to permit completion of the work is said to be plastic, it may be said that plasticity is a property inherent in the lime itself and has nothing to do with consistency. Duff A. Abrams, of the concrete committee, submitted the definition "The relative plasticity or workability of freshly mixed material" and explained the work that has been done of late to determine that quality in concrete. It is evident that this committee considers the term in its practical application as describing a readily observable, though not necessarily readily measurable condition, and not as a physical property. Prof. E. C. Bingham (Lafayette College) after defining in the terms of physics the qualities viscosity, plasticity, mobility, etc., said that the present looseness characterizing the word "consistency" would be avoided if its use were restricted to the definite meaning of the reciprocal of mobility, for which there now exists no term. Dean A. N. Johnson said that consistency should be used as indicating a condition and not a property, and that a definition should be made on the basis of determining the phenomenon which brings about the condition.

The discussion may have served to bring out more clearly a divergence in view between the physicist and the man interested in producing and using materials, but it did little to clarify the understanding of the word in either of the two groups.

Concrete Brick Postponed—Committee C-4, on Brick, put on record the six standard sizes for paving brick adopted by the conference organized by the Department of Commerce, and voted to submit to the letter ballot of the committee the suggested specifica-

tion for concrete brick which the committee rejected last year. This postpones for one year consideration by the society of the concrete brick specification which the advocates of that type of brick claim was justified by the recent tests by Columbia University (see *Engineering News-Record*, May 31, 1923, p. 959).

Cement and Concrete—Little developed in the field of cement and concrete. Committee C-1, on Cement, had no recommendations but reported that it was continuing the study of the compression test for cement and also studying the general nature of cements with a view to improving specifications. Committee C-9, on Concrete and Concrete Aggregates, submitted a revised tentative specification for aggregates, which includes a new section on grading of fine aggregate and coarse aggregate both, changed from circular to square openings in grading the coarse and admitted air-cooled blast furnace slag as a suitable aggregate. In this latter connection the report says:

In regard to the changes which have been made in the paragraphs dealing with coarse aggregates, the recognition of air-cooled blast-furnace slag is the most important. A large amount of test data has shown this material to be acceptable as concrete aggregate, and there is also a large amount of data from the field in testimony of the durability and permanency of slag concrete structures. The only special restriction which has been put upon this material is a limitation upon weight per cubic foot, the specified weights being high enough, it is believed, to exclude undesirable material. No restriction has been placed upon the sulphur content of slag, for the reason that inspections made by members of the committee of reinforced slag concrete structures in the course of demolition showed no corrosion of reinforcement that could be attributed to slag, nor is there any published evidence that such corrosion has been observed, so far as the committee is aware.

In a report for the Joint Committee on Concrete and Reinforced Concrete, Richard L. Humphrey, chairman, told of the status of that committee's final report. He said that the committee did not intend to cover all phases of the uses of cement but merely intended to bring the old report to date. He thought that there had been fair criticism of the committee's provisions on quality as not being entirely practicable and said that the committee was considering that part of the report with the greatest care. It is intended now to review all the criticisms of the report and to prepare a final report which should be ready next year. As a final word he said the committee considered itself in a judicial position, not to formulate opinion but to crystallize practice.

Several excellent papers on concrete were presented at one of the sessions. They include a study of calcium chloride as a curing agent and accelerator, by H. F. Clemmer and Fred Burggraf, of the Illinois Highway Division; the fatigue of mortar, by R. B. Crepps, of Purdue University; a new test for workability by J. C. Pearson and F. A. Hitchcock, of the Bureau of Standards; and a paper on blast furnace slag aggregate by Raymond Harsch, of the Bureau of Public Roads. Abstracts will appear in an early issue.

Behavior of Concrete—Great interest was aroused in a symposium on the service study of concrete. Although this was set for the last night of the meeting some 200 members were present. The subject of the symposium was "What Properties of and Methods of Making Concrete Require Further Investigation?—A Discussion of the Requirements of Concrete to Meet the Many

Varieties of Service Conditions. What Can Be Learned From Behavior of Actual Structures?" The scheme of the discussion was first to consider the constituents of concrete and its methods of making, in the light of service requirements, with a view to developing future possibilities in cement, aggregates and proportioning. This was followed by a study of service conditions in roads, sea water, alkali water and under the normal attacks of weather.

The subdivisions, briefly considered, were as follows: P. H. Bates, (Bureau of Standards) discussed the behavior of concrete under three conditions of exposure—ordinary air moisture, non-sulphate water and sulphate water, and considered the cement requirements for each. His conclusions are that for each there are possibilities of improvement in the cement itself, though the needed improvements may differ in detail for different uses. He recommended a new slogan "Concrete for Study." Duff A. Abrams (Structural Materials Testing Laboratory) discussed aggregates. He said that the strength and resistance of concrete depended more on proportioning and methods than on aggregate, which if well graded, clean and structurally sound could be made to produce good concrete regardless of other qualities. He emphasized, therefore, further study of methods of manufacture. R. B. Young (Hydro-Electric Power Commission of Ontario), considering methods of proportioning and mixing, noted the complications of applying the newer methods in this field, emphasized the necessity for more careful measuring and for more study of the mechanism of mixing and of the influence of plant design. Arthur P. Davis (Washington, D. C.) reported the behavior of mass concrete under the varying service requirements of the Reclamation Service. P. J. Freeman (Pittsburgh) cited several cases of bad disintegration and concluded that density is the great desideratum, not strength. A. T. Goldbeck (Office of Public Roads) cited the numerous details of design and construction of concrete roads that have resulted in undesirable conditions, with a view to pointing out proper methods. S. C. Hollister (Philadelphia) summarized the knowledge on the behavior of concrete in sea water and G. M. Williams (University of Saskatchewan) of concrete when exposed to alkaline conditions.

This comprised the formal reports. Some twenty informal discussions followed. They, together with the main reports, will be abstracted in a later issue. As the chairman, Prof. A. N. Talbot, said at the close of the session, the symposium was worth while as a resumé of the present state of knowledge of concrete and as an indication of where to look for improvement. It is perhaps pertinent to remark that the high points of the discussion were the contention of Mr. Bates that present cement standards do not satisfactorily cover all kinds of service and that different cements for different purposes may prove advantageous; the opposition, based mostly on economic grounds, by the cement manufacturers to multiple standards; the statement of the manufacturers that they are now engaged in a thorough chemical and physical study of the nature of cement which conceivably may lead to an improvement in the product; and finally the repeated conclusions of discussors that improvement of concrete lies mostly in the bettering of workmanship, though there are many instances of poor concrete not altogether explained on this ground.

Abstracts of Test Methods and Results

Principal Points in a Series of Papers Read Before the Atlantic City Convention of the American Society for Testing Materials, June 25-29

Accelerometer for Measuring Impact

Abstract of a Paper by Earl B. Smith

THE force of impact in most cases cannot be measured directly as can be done by weighing a static force. It is a product of mass and acceleration, and the most convenient and direct method of determining this impact value is by means of an accelerometer which may be attached directly to the moving body or hammer and which will indicate the acceleration value.

FIG. 1—ACCELEROMETER WITH OPTICAL LEVER

FIG. 2—ACCELEROMETER ARRANGEMENT

The essentials of a small accelerometer are shown diagrammatically in Fig. 2. Within a rigid frame is mounted a steel beam, *B*, supported only at the two ends. At the center of the beam is attached a mass, *W*. A toggle, *C*, is provided which will hold the beam at any maximum deflection position until the amount of deflection may be measured with the micrometer dial. In use, the accelerometer is rigidly attached to the moving body or hammer, with the plane of the beam *B* at right angles to the direction of motion or to the line of action of the force to be determined. When the velocity is constant there will be only the static deflection of the beam, but when the velocity is changed and the acceleration is negative the beam will be further deflected because of the inertia of the mass *W*; that is, under the influence of a deceleration (negative acceleration) the mass *W* will exert a force which will deflect the beam. By properly proportioning the beam and its attached mass, the range of the instrument may be made suitable for any desired condition. The deflection of the beam must be restricted to very small limits; it is kept within about 0.015 in. and the exact amount is read from a micrometer dial or by means of an optical lever system.

An improved design of instrument is shown in Fig. 1. In this case the beam *B* has fixed end supports and its maximum deflection is 0.003 in., which is measured by the movement of a beam of light giving a magnification of about 800. The stem *W*, which is also the weight attached to the beam, operates a small oscillating mirror at *M*. The light from a small electric lamp is focused by the lens *L* onto the small mirror and reflected to the scale *S*. At *R* is a stop or brake which holds the small mirror in its deflected position after the deflection of the beam until the reading may be made from the scale. A small push rod allows the brake to be released and the mirror returned to the zero position. The weight of the stem and parts *W*

supported on the beam, including one-half the weight of the beam, is 0.0249 lb.; the static weight necessary to deflect the beam and move the light ray on the scale 1 in. is 0.650 lb.

A calibration curve for this instrument compared with the results from a space-time curve indicates a reliable degree of accuracy. The range of this accelerometer is from about 2 to 25 times the acceleration of gravity. Continuous records may be obtained by a photographic recording attachment.

These accelerometers were originally designed for use at the Bureau of Public Roads on autotruck wheels and axles in connection with special investigations of the impact of trucks on roads.

Endurance of Duralumin, Electron and Manganese Bronze

Abstract of a Report by R. R. Moore on Investigations by the Engineering Division of the Air Service at McCook Field

ENDURANCE tests on three of the most important light alloys were carried out by means of a rotating-beam machine, which subjected the test bar to alternating stress. The general character of the results is shown by the curves reproduced herewith. In contradistinction to the results found for steel and other ferrous materials by H. F. Moore at the University of Illinois, in whose tests a definite

ALTERNATING-STRESS TEST RESULTS

Upper diagram, manganese bronze and electron, plotted on semi-logarithmic paper; middle diagram, duralumin plotted on logarithmic paper; lower diagram, duralumin on logarithmic paper, which fails to reveal important features of the curves.

endurance limit was found, that is, a stress below which the material would stand an indefinitely large number of stress reversals, the McCook Field tests indicated that beyond an early endurance limit there is a further dropping off of the curve, at least in the case of duralumin tested "as received." It is concluded that the endurance limit of duralumin cannot be obtained by tests carried only to 10,000,000 cycles.

The endurance limit for these metals was not found to bear any constant relation to other physical test properties. The endurance limits from the tests are reported to be the following:

Manganese bronze	15,000 lb. per sq. in.
Electron metal	17,000 lb. per sq. in.
Duralumin, as received	14,000 lb. per sq. in.
Tempered at 920 deg. F.	12,000 lb. per sq. in.
Annealed at 700 deg. F.	10,860 lb. per sq. in.

Vibration was not found to affect the results materially. All the tests were run at a speed of 1,500 r.p.m., which is above the first critical speed for the size and shape of specimens tested, but yet resulted in considerable vibration in some of the specimens.

Effect of Wood Preservative Treatment Tested in Fungus Bed

Abstract of a Paper by Cloyd M. Chapman

TEST specimens of wood treated by different preservative methods were exposed in an outdoor fungus bed ten years ago. An initial report on this test rendered in 1915 is now supplemented by a final report. The fungus bed (outdoor) was prepared by mixing decayed wood and dry pulverized sheep manure with well sifted soil. Twelve-inch stakes, $1\frac{1}{2} \times \frac{1}{2}$ in., pointed at one end, were driven about 9 in. deep into this bed. Oak, cypress, spruce and yellow pine were used. The preservatives were applied in three ways: cold dip for 15 sec., hot dip for 1 min., and hot immersion for 1 hr. followed by cooling in the preservative. Thirty preservatives were used, including various tar products, mineral, vegetable and animal oils, and solutions of inorganic salts.

The results indicate, according to Mr. Chapman, that coal-tar and water-gas-tar derivatives are superior to the other classes of materials used. These creosotes show a higher average degree of protection than any other material tested. Among the creosotes themselves there are some considerable variations; in general, the higher-boiling fractions seem to be the more effective. None of the preservatives gave permanent protection against decay under the conditions of this test.

There seems to be but little difference between the cold-dip and the hot-dip treatment. Hot immersion, or boiling, is very much better (though at much higher cost), but even the approximate saturation which may at times be attained by the boiling treatment does not render the wood immune from decay in the course of time.

Properties of Slate

From a Paper by Oliver Bowles, Mineral Technologist, U. S. Bureau of Mines

ASERIES of roofing slate recently tested showed a modulus of rupture of 8,200 lb. per square inch, which is about five or six times the strength of average sandstone or limestone and three or four times that of average marble. Ribbons in the slate do not necessarily affect the strength, as was shown by fractures crossing the ribbons in a special set of tests of slabs of ribboned slate at the Bureau of Standards. The porosity of slate averages 0.38 per cent, which means that average slate is well adapted for sanitary uses. The coefficient of expansion of the material is 0.000005 (Watertown arsenal tests).

Production and market requirements of slate do not permit of reducing the number of sizes of roofing slate. In Cincinnati, Ohio, and Galveston, Tex., the principal demand is for 10 x 12-in. slate; in Chicago, 10 x 16-in.; in Columbus, Ohio, 12 x 24-in. A variety of sizes permits the demands

of various localities to be suited and also permits of utilizing the raw material to best advantage with a minimum of waste.

In laying slate roofs a 3-in. head lap should be the universal standard. The nails should be as permanent as the slate.

Abrasion resistance of slate has not been sufficiently studied, but experience shows that there are very great differences in the resistance of various slates to wear, when used as stair treads and the like.

Standardization is needed in many directions in connection with slate, and much experimental work should be conducted as a basis for correct and logical specifications. The need of specific requirements is outstanding in the matter of thickness, size, and color stability of roofing slate, quality of blackboard slate, strength and abrasion of structural slate, and insulating value of electrical slate.

A Successful Distant-Reading Extensometer

Abstract of a Paper by O. S. Peters and R. S. Johnston

A REMOTE-READING extensometer has been developed at the Bureau of Standards which utilizes the pressure-resistance or displacement-resistance characteristic of a stack of carbon plates. Heretofore attempts to utilize this

FIG. 1—SINGLE STACK OF CARBON PLATES AND ITS DISPLACEMENT-RESISTANCE CURVE

characteristic of carbon for engineering measurements have been unsuccessful because of erratic behavior of the resistance of the carbon stack, hysteresis effects, and the non-linear relation between displacement and resistance. The resistance of the stack has now been stabilized and changes of resistance with changes of pressure made reproducible, by mounting the stack in a frame in such a way that it is always under considerable pressure, and confining the range of change of pressure within narrow limits; the pressure on the stack is applied axially, and great care is exercised in assembling in order to make transverse forces on the carbon contacts as small as practicable. Hysteresis effects, which cause the resistance of the stack corresponding to a given pressure to differ for increasing and decreasing readings, have been made negligible by using a mounting frame without mechanical joints, as experiment showed that the cause of the hysteresis lay in these joints rather than in the stack itself. The non-linear characteristic has been made straight by mounting two stacks of plates in each instrument in such a way that the resistance of one is decreased and the other increased by the force or displacement under measurement; the cumulative change of resistance of the two stacks has been found to be proportional to the change of displacement or pressure, with the ultimate result that an instrument with substantially a linear calibration curve is obtained.

A single stack of carbon plates mounted in a steel frame as shown in Fig. 1 is placed under pressure from the spring-like part *H* of the frame, the pressure being adjusted by set screws at either end. The carbon plates *B* are ring-shaped pieces, about fifty in number, held between mica end plates and connected to a circuit by brass contact disks *C*. The mirror and magnetized rod at the right are an auxiliary

calibrating device. This stack gives the displacement-resistance curve shown in Fig. 1; the resistance changes about 46 per cent for a change in length of the stack of 0.00217 in., and is practically free from hysteresis effect, shown in coincidence of increasing and decreasing values.

A complete extensometer is shown in Fig. 2. The solid steel frame *A* has a cantilever arm *B* integral with the

FIG. 2—STRAIN INDICATOR WITH DOUBLE STACK

frame and notched near its upper or fixed end. The rod *C*, threaded into the cantilever, moves in the guide tube *D*. The stacks of carbon rings, assembled on each side of the cantilever, are arranged as two sides of a Wheatstone bridge circuit; a three-conductor wire lead connects them to the indicating device. The span covered by the instrument shown is 8 in., though others have been made ranging in span from 2 to 24 in. with full-scale readings from 0.002 to 0.024 in.

For use the indicator is attached to a member by means of clamps, sharp steel points at either end of the instrument being forced into punch marks in the metal. The force required to operate the instrument depends largely upon the resistance of the cantilever to bending, but this need not exceed 10 lb. as a maximum, which is a small portion of the tensile stress usually involved.

A typical calibration curve for such an instrument is shown in Fig. 2, which exhibits the linear characteristic resulting from the use of the two stacks of plates. The hysteresis effects do not in any case exceed 4 per cent of the full range of the instrument and in most cases are less than 2 per cent.

Twelve instruments of this type have been in use at the Bureau of Standards in tests of 143 lattice girder members which were full-size duplicate parts of the duralumin frame construction of Fleet Airship No. 1, and on fourteen test specimens of large columns for the Delaware River Bridge Commission. Some tests on bridges have been made to verify the applicability of the instrument to field service. Records taken on a steel truss bridge while trains were passing showed vibrations ranging between 2 and 100 cycles per second. With vibrations of this character, repeated tests have shown very little effect on the calibration, and as the free period of the different parts of the apparatus which could introduce sympathetic vibrations was adjusted above 300 cycles per second, or three times the highest frequency recorded, it appears that the deflections must be proportional to the strains.

They have also been applied to the measurement of stresses in airplane stay cables during flight. A similar application has been made to airships. A carbon resistor device for recording the pull on the pressure arm of a machine for testing brake band material has been in service for some months with good results. Experimental applications have been made to the measurement of pressures ranging from a few millimeters of mercury to 40,000 lb. per sq. in.

* * *

Notes on Other Papers

IN compression tests of babbitt metals, John R. Freeman, Jr., and Paul F. Brandt, of the Bureau of Standards, tested the effect of varying length of specimen on resulting values of compressibility obtained. They found that the unit deformation is practically independent of length for ratios of length to diameter ranging from 1:1 to 3:1, and that the unit deformation for the central $\frac{1}{2}$ -in. length of a 3-in. specimen is the same as for the central $2\frac{1}{2}$ -in. length. The total deformation is a function of time of loading, but for loads below appreciable yield a loading time of 30 sec. to 3 min. is sufficient to give reasonably precise results.

Some data on metallurgical coke were given by G. S. Perrott and A. C. Fieldner, of the Bureau of Mines. The crushing strength of the coke is found to range from 400 to 2,000 lb. per square inch, which gives a large factor of safety, as the load on the coke in the hearth of a blast furnace averages only 35 to 40 lb. per square inch. The "shatter test" values for coke vary over a large range and depend upon the size of piece tested, so that "it would seem that considerable variations in the shatter test results have little influence on blast furnace performance." The true specific gravity of the metallurgical cokes ranges from 1.84 to 2.10, and the apparent specific gravity from 0.80 to 1.15. The porosity ranges from 40 to 60 per cent, averaging 45 per cent. It is concluded that aside from chemical analysis we are not at present in a position to write specifications for metallurgical coke. Practice shows that any coke having an ash content of less than 13 per cent, sulphur less than 1.25 per cent, true specific gravity over 1.80, porosity less than 55 per cent, and a shatter test over 40 per cent will be satisfactory for blast furnace use.

Quite variable relations between different consistency tests—the cube-in-water softening point, the ring-and-ball softening point, the float test, the needle penetration—were found in tests of a variety of tar residues, at the Michigan State Highway Laboratory, reported by J. W. Kennedy. The relation between the different test values depends largely on the amount of free carbon in the tar.

Discussing the question of whether chemical requirements should be included in cast-iron specifications, Robert Job and Richard Moldenke agreed that certain chemical specifications are necessary to assure proper results in the production of castings. The main point of the argument was that physical testing of cast iron is not capable of determining satisfactorily all the qualities expected of the finished article. Sulphur and phosphorus are the chief items that should be limited. Combined carbon may also have to be limited in such iron as car-wheel iron.

(Concluded next week)

Letters to the Editor

This department aims to be a forum for the discussion of the views of engineers and contractors. The range of interest should be as wide as possible. Contributors are, therefore, asked to make their letters short.

A Notable Dam

Sir—Mr. Gutmann's description of the high multiple arch dam in Italy (*Engineering News-Record*, May 10, 1923, p. 820) is of great interest to hydraulic engineers.

This dam is remarkable not only for its great height but also for the economy combined with a large factor of safety which this type of dam possesses. Noteworthy is also the steep upstream slope (57 deg. as against the usual 45 to 50 deg.).

Mr. Gutmann refers to the dam as being 200 ft. high. As a matter of fact, the dam rises about 200 ft. above stream-bed, and the foundation of the five highest buttresses extends in an average approximately 28 ft. deeper, thus making the height of the structure 228 ft. Some portions of the buttresses had to be carried to still greater depth, as stated by Mr. Kambo, the designer of the dam. If, therefore, the height of dam is calculated according to the principles expounded in your recent editorial, "How High Is a Dam?" (Nov. 2, 1922, p. 728) the maximum height of the Tirso multiple-arch dam would be 242 ft. by figuring the overall height from the deepest point of the foundation (El. 39.0 m.) to the top of the solid parapet (El. 112.9 m.).

The use of hand-laid stone masonry for the buttresses may have been justified in a country which is noted for its highly skilled stone masons.

For our conditions, concrete would be much preferable both for economic and structural reasons. Mr. Gutmann states that in the construction of the Tirso dam about 20,000,000 lire (nearly \$1,000,000 at the present rate of exchange) was saved as compared with the cost of a gravity dam. In order to fully appreciate this remarkable saving, it must be considered also that the factor of safety of a multiple-arch dam is much higher than that of a gravity dam, because by virtue of the sloping upstream face the direction of the water pressure is inclined towards the foundation, and overturning of such a multiple-arch dam is inconceivable. Furthermore, while engineers may argue with regard to the necessity of designing a gravity dam so as to resist under-pressure, there is hardly any need of considering uplift in the case of multiple-arch dams, if the arches are well keyed into deep rock-trenches. For obvious reasons, no under-pressure can exist under the buttresses.

The construction of the Tirso dam marks a great step forward in dam engineering and will pave the way for the construction of high multiple-arch dams also in this country.

San Francisco, Cal.,

May 24, 1923.

Consulting Engineer.

Unbalanced Bids

Sir—Under the caption "False Statement of Quantities Unbalances Bids," Clinton L. Bogert in *Engineering News-Record*, June 7, 1923, p. 998, discusses a question of great interest to all construction engineers and contractors. Obviously if the schedule of quantities submitted constitutes a correct statement of fact, there could be no possible advantage to a contractor in an unbalanced bid. Therefore, the schedule of quantities against which bidders are invited to set unit prices should cover only such items as are known with reasonable definiteness and accuracy. Minor items not susceptible of even preliminary determination may well be set down so as to afford an adequate conception of the magnitude and scope of the undertaking as a whole but should have set against them unit prices which the owner agrees to pay for the same. An owner is largely helpless in the hands of a dishonest or incompetent engineer or architect, but if these trusted officials are

honest and competent there should be little or no unbalancing of bids. It would be unwise for a contractor to accept any quantity estimate without satisfying himself that it is reasonable and, if his investigation leads him to suspect that the quantities are incorrect he surely could not be expected to set aside his own judgment for the sake of submitting a balanced bid.

Let every engineer and architect, before he sends out a call for bids, endeavor to put himself in the place of the bidder with respect to each and every division of the work with the purpose of determining to his own satisfaction that the specifications and plans would enable him to prepare an accurate estimate of cost which he would be willing to back, not only with his reputation but with his money. When, as is frequently the case, his practical experience has not been such as to afford proper basis of judgment, let him call upon some one of the necessary practical experience to go over the proposition and advise him from a practical standpoint. If such were the practice there would be very few unbalanced bids submitted.

In conclusion it may be said that if every engineer and architect would undertake conscientiously to give his client even approximately that degree of responsible service that he expects to exact from the contractor, construction work would be much more economically done, owners would get greater value for their money and contractors would be enabled to make an honest living without being forced to pit their wits against those of agents in authority.

San Francisco, Calif.,

June 14, 1923.

E. T. THURSTON,
Consulting Engineer.

Test of Acid in Dewatering Activated-Sludge at Plainfield Sewage-Works

Sir—In an article in *Engineering News-Record*, March 22, p. 522, C. Lee Peck refers to the "success" of sludge dewatering experiments at Plainfield making use of sulphur dioxide gas. The "success" was a great surprise to me but I passed the matter up at the time feeling that it was possibly within the limits of exaggeration permitted to "efficient sales engineers." However, it seems that the prestige of the *News-Record* together with the faith which has come to be attached to statements from the Plainfield plant has given the statement more weight than the facts will bear.

The only tests made at Plainfield were two runs of 50 and 110 minutes respectively. No pH or other control determinations were made. The sludge to be treated and the effluent from the machine were sampled every ten minutes during the runs for solids, and each wheelbarrow of dewatered cake was sampled and moisture was determined in the mixture of all samples with results as follows:

Length of Run, Minutes	Sludge Treated, Gal. per Hr.	Percentage Solids in—		
		Untreated Sludge	Cake from Dewaterer	Effluent from Dewaterer
110	2,000	4.0	12.0	3.4*
50	1,100	4.9	15.4	3.4*

* Solids in effluent from dewaterer constitute 80 and 70 per cent respectively of the original solids in the sludge and are in a colloidal state of division which would make their further treatment almost impossible.

These are positively all the data on the Plainfield tests and I consider them too limited to allow of deductions being made pro or con.

JOHN R. DOWNES,

Superintendent Plainfield Sewage-Works.

Green Brook Park, Bound Brook, N. J., May 9.

[What Mr. Peck said about the Plainfield plant was embraced in a brief reference to experiments there and at Brooklyn and Indianapolis, as follows:

The MacLachlan process seems to have solved the problem of raw sludge disposal. MacLachlan's experiments at Indianapolis, Brooklyn and Plainfield, N. J., have demonstrated that such sludge can be rendered inoffensive and easily drainable. The sludge is acidulated by injecting hot sulphur dioxide gas. When a hydrogen-ion concentration of pH 3.8 is approached the sludge turns straw color, the colloids coagulate. In this condition it dewateres readily. —EDITOR.]

News of the Week

CURRENT EVENTS IN THE CIVIL ENGINEERING AND CONTRACTING FIELDS

News Brevities

The Alaska Railroad Has Organized a river boat service to operate boats from Nenana on navigable rivers and to connect with the small boats on the upper Tanana, Tolorana, Koyukuk, Iditarod, and Innoko Rivers.

At the Sherman Island Development, Glens Falls, N. Y., water was turned into the power canal on June 25. This is the preliminary step in putting the first units of this 50,000 hp. power plant into operation.

Grade Separation on the Grand Trunk Ry. through the city of Detroit, Mich., will be started in the near future, and will be carried on until all the grade crossings from the river north to Ferry Ave. have been eliminated.

An Elevated Water-Supply Tank at Fox Lake, Wis., recently failed by the bottom falling out. According to W. G. Kirchhoff, consulting engineer, Madison, the tank had never been painted since its erection and corrosion of the bottom is believed to be responsible for the failure.

The Tax Exemption Period on new dwellings in New York City will be extended to Jan. 1, 1932 by an ordinance adopted by the Board of Aldermen on June 26, and signed several days later by Mayor Hylan. The extension is based on recent state legislation following two court decisions, the first of which denied and the second upheld the constitutionality of the original statute (See *Engineering News-Record*, March 29, p. 598, and May 24, p. 943.)

An Agreement Between the State of New York and the Federal Power Commission whereby the state can drop its suit against the federal water power act without the surrender of authority by either side, seems now assured. Such an agreement will be the result of a conference now in progress at Washington at which all the questions at issue are being discussed with a view to having the commission render certain opinions which will clarify the whole situation.

Another Trunk Railway From New York to the west is proposed by A. H. Smith, president of the New York Central, in suggesting that the Central Railroad of New Jersey be consolidated with the New York Central. Mr. Smith stated that traffic is increasing at such a rate that an additional through line will be necessary within the next four years; that the New York Central has a line from Ashtabula, Ohio, to Newberry Junction, Penn., which is not being used to full capacity, and that by connecting this line to the Jersey Central a new and direct line to the west could be developed.

City Managers Association To Meet With Municipal League

The City Managers Association and the National Municipal League will hold their meetings at the New Willard Hotel, Washington, D. C., Nov. 13 to 17, the conventions overlapping on Nov. 15. John G. Stutz, Lawrence, Kan., is secretary of the managers, and H. W. Dadds, 261 Broadway, New York City, of the league.

High Bridge Not to Be Destroyed

Owing to the report of an engineering committee that High Bridge, spanning the Harlem River near 160th St., New York, can be reconstructed so that navigation beyond it will be unimpeded, the Board of Estimate and Apportionment last Friday decided that the historic structure should not be torn down. The advisory board of engineers and architects headed by Edwin S. Jarrett, presented to the city a plan whereby three main river spans would be replaced by a single steel arch, thus eliminating from the Harlem channel the three piers now obstructive to navigation. This committee advised the city that it would cost about \$1,000,000 more to tear down the structure and replace it by an invert or tunnel under the Harlem, reconnecting it with the Croton aqueduct system, than it would to remodel and reconstruct the existing bridge. The committee of engineers has estimated that it will cost only \$716,000 to reconstruct, whereas a new structure, together with demolition of the old bridge, would entail an expenditure of about \$1,700,000.

On the committee serving with Mr. Jarrett were Donn Barber, Ralph Modjeski, A. Lincoln Bush, J. Vipond Davies and William J. Wilgus.

East St. Louis Enjoins Sanitary Sewer Excavation

A temporary injunction restraining the East Side Levee and Sanitary District from continuing work of digging the drainage canal known as Project No. 12 within the city limits of East St. Louis, Ill., was issued June 23, by Judge Silas Cook of the East St. Louis City Court.

The city petition presented by Special Counsel Thomas Webb and Corporation Counsel R. V. Gustin contends that no permit to dig in the city limits has ever been obtained and that no condemnation proceedings were ever instituted to fix the value of the property which will be damaged by the construction. It further alleged that the crossing of State street would necessitate an excavation 100 ft. wide and greatly impede traffic between East St. Louis and Belleville, Ill.

The injunction is made returnable in September, and the city at that time will attempt to have it made permanent. A. V. Wills and Sons, and H. J. Sternberg, the contractors, have stopped work.

No New Light Shed on Cause of Elevated Disaster

Many Investigations Now Being Carried on By Prominent Engineers—Transit Commission Busy

There has been little progress this week towards the determination of the cause of the fatal accident of June 25 at Atlantic and Flatbush Aves., Brooklyn, in which a two-car elevated train derailed and fell 30 ft. to the street. The primary cause is generally conceded to have been the presence of some object on top of the frog of the crossover switch, and as a bolt was found to be missing from the brake rigging of the leading truck of the forward car, and as the motorman stated that the brake on that car failed to work, an effort is being made to prove that this missing bolt dropped on the frog and caused the derailment. The cause of the fatalities, the falling of the cars into the street, is also still unknown. The supposed "rotten" condition of the wooden guard rails has frequently been stated as the reason for this part of the accident, but in view of the fact that the derailed truck was kept on the deck by these very guard rails it is difficult to see how they are responsible. Moreover the guard rails were not in such a serious condition as some people would like to believe. The report of the Transit Commission inspectors made a few months ago states that out of 230 timbers on this section of the elevated only 3 needed renewal.

B-M. T. INVESTIGATION

The B-M T. Co. is conducting an investigation into the cause of the accident and have retained Dwight P. Robinson, J. Vipond Davies, and George H. Pegram to make an examination of the structure at the point of the derailment. The company has also engaged the firm of Parsons, Klapp, Brinckerhoff and Douglas, consulting engineers, to make an examination of the timber deck of the entire elevated structure. The Transit Commission is also conducting an investigation and are turning over all their reports to the district attorney who in turn has engaged John C. Brackenridge to make a report.

Since the fatal accident on June 25 on the Brooklyn elevated railroad a rumor has been circulating to the effect that the Broadway line between Alabama Ave. and Cypress Hills vibrated so much under the steel trains as to be unsafe. Robert Ridgway, chief engineer of the Transit Commission, in commenting on this states that before the operation of steel cars was permitted on this line extensometers were used to determine the stresses in the structure under the increased loading and that the results of the tests so made indicated that steel cars could be operated on this line with safety. He also stated that since operation started further tests had been made which confirmed the results of the original tests.

Southwest Water-Works Association Meets

200 Attend Gathering at Wichita Falls, Texas—12 Technical Papers Are Presented

Engineering News-Record Staff Report

Two hundred water-works officials and others interested in the Southwest Water Works Association met June 18-21 at Wichita Falls, Tex., and discussed a dozen technical papers presented at the five sessions. The papers, which covered a wide range, were prepared almost entirely by operators and water-works engineers from the eight states comprising the association's field. Municipal versus private ownership and how to eliminate politics are still being discussed vigorously in the Southwest.

The accountants got real assistance from R. O. Grant who has just installed a combined billing and book-keeping machine at Wichita Falls. His paper was followed by a demonstration. The chemists were served by a paper on "Algae Treatment at Fort Worth" by W. H. Mahlie, chemist, Fort Worth, as well as a discussion on tests for overdosing with alum and chlorine. V. M. Ehlers, state sanitary engineer of Texas, by cartoon effectively illustrated various means by which waters are polluted, particularly small well supplies, and proper methods of pump settings and well location and protection. For the superintendents perhaps the most appealing papers were by J. W. Hockaday, superintendent, Cleburne, Tex., on the "Dollar Value of Meter Maintenance" which gave the return for seven years, and another showing a new service distribution chart by S. L. Williams, superintendent, Wichita Falls.

ENTERTAINMENT FEATURES

The Southwest Association always makes much of its entertainment features and the hospitality of Wichita Falls permitted none but superlatives in describing these features. The high water mark was an all-day 100-mile automobile trip to the local water pumping plant and filters and then over the \$4,500,000 Wichita County Irrigation Project comprising an 85-ft. hydraulic-fill storage reservoir (535,000 acre-ft. capacity) and an earthen diversion dam filled by teams, graders, gas and steam shovels and elevating graders with the compaction by irrigating the surface in 1-ft. layers. This project is financially carried by District 1 comprising the city of Wichita Falls which has little irrigated land. The city badly needed an augmented water supply. The barbecue provided by the Callahan Construction Co., contractors, at the storage dam camp furnished a fitting setting for a description of the project by R. A. Thompson, chief engineer, utilizing a truck for a rostrum. Two of the service gates in the dam, which is nearly completed and has been impounding some of the extraordinary floods of the southwest country, were opened for demonstration of the clockwise swirl in the outlet spillway. Although the main dam is being topped out by the hydraulic dredge the sheer-board method of building the lifts in the main structure, heavy 30-in. repropping of country rock and utilization of a gas shovel in throwing up the toes were visible but not the puddle core as the dam is

F. A. E. S. Protests Ousting Davis from Reclamation Service

The Federated American Engineering Societies, through its committee on public affairs, has filed a protest in the office of the Secretary of Interior against the ousting of Arthur P. Davis as director of the Reclamation Service (see *Engineering News-Record*, June 21 and 28, pp. 1099, 1110, 1138 and 1139). On the return of Secretary Work from his Alaskan trip with President Harding the committee will request Secretary Work to explain his action.

Exploding Brick Pavement Wrecks Auto in Illinois

Mr. and Mrs. Earl Rahel of Paris, Ill., narrowly escaped serious injuries June 22 when a section of brick paving on the Chicago road near Paris expanded and buckled under their automobile. The explosion of the road was heard for some distance, bringing farmers from their fields. The concrete foundation was torn out, the front wheels of the automobile were torn off, a tire was ripped from a rear wheel and the machine was thrown to one side of the road. Mr. and Mrs. Rahel were slightly injured by fragments of brick. The intense heat caused the accident.

To Remove Old Superior Viaduct

An order of the War Department has been served on the city of Cleveland to remove the river portion of the old Superior St. viaduct. This structure was superseded by the new High Level viaduct six or seven years ago, but continued in existence largely to serve one or two property owners who had obtained access rights to the deck of the viaduct many years ago. The structure deteriorated to the point of becoming unsafe, however, and was closed as unsafe last year by order of the mayor. The War Department's order is issued in the interests of navigation, and affects the draw span and its support and all parts of the structure that project over the river. The viaduct was built forty-five years ago.

above the spillway level. The whole work will be near completion in two months. The return trip afforded inspection in many places of the 1,000-sec. ft. 163-mile canal and structures of which the special features are the consolidation of drops, crossings, wasteways and overflows in various combinations.

The newly elected officers are as follows: President, F. N. Lawton; vice-president, W. F. Anderson; governors, J. W. Hockaday, Texas; E. O. Fowler, Louisiana; R. M. Foster, Jr., Arkansas; H. A. Gallagher, Missouri; B. L. Ulrich, Kansas; G. F. Reinhart, Oklahoma; Joe W. Kelly, New Mexico. R. D. Morgan, Mexia, Tex., was re-elected secretary-treasurer.

Exhibits were put on by twenty-seven members of the Waterworks Manufacturers Association including meters, meter boxes, hydrants, pump valves, chlorinators, chemicals, brass goods, air-lift pumps, filters, pipe cleaners, cast-iron and reinforced-concrete pipe, packing and calking material and pipe cutters. An evening session was given up to a description and moving picture of the making of centrifugal cast-iron pipe.

A. G. C. Adopts Standard Form for Advertising Construction Work

The Associated General Contractors has, through its Executive Board, adopted the standard form of official advertisement for construction work which is herewith reproduced. The legality of the form has been verified, and an endeavor will be made by the Association to have the form, which it is believed, will reduce waste and expense, adopted throughout the country.

Proposed Standard Form of Official Advertisement for Construction Work

(Date Bids Are Wanted)

(Location of Work)

(Type of Work)

(Location of Authority for Advertising)

Sealed proposals for the construction of—
_____ will be received by the—
_____ of the—

(Public Authority) (Political Subdivision)
at their office. (Address) (Street) (City) (State)

until _____ M. (Date) (Month) (Year) and
(Hour) (Date) (Month) (Year) and
then publicly opened.

The principal (dimensions or) quantities involved are approximately as follows:

Payments to be made _____ in
(When)

(Cash, Bonds or Special Tax Bids)
retaining only _____ % of the value of materials delivered and work performed, but not exceeding _____ Dollars

(\$ _____) until practical completion of the work.

Limiting funds available _____ Dollars (\$ _____). The site or right of way for the construction work _____

(If or Will Be) _____ available _____ (Immediately or State Date)

Time of completion _____ (Insert Date or Number of Working Days)

Plans, specifications, also forms of proposal, contract and Surety Company Bond or Deposit of Public Securities, amounting to _____

(Dollars or Per Cent of Bids)
may be secured by addressing the undersigned or the Designer.

(Address) (Street) (City) (State)

upon deposit of _____ (Actual Cost of Printing and Postage)

Dollars (\$ _____) which will be refunded upon return of plans within fifteen days after bidding date. Each bid must be accompanied by a statement of financial responsibility and previous contracting experience and references and _____

(Certified Check or Bid Bond) for _____ Dollars (\$ _____)

which will be returned to unsuccessful bidders within ten days after bidding date.

Right is reserved to reject any and all bids, or waive any informality in any bid.

Southern Appalachian Power Conference Meets

Nearly One Hundred Delegates Discuss Power Situation in the South—Recommendations to Congress
Special Correspondence

The second annual meeting of the Southern Appalachian Water Power Conference was held in Asheville, N. C., during June 25, 26 and 27. Nearly 100 delegates attended. The Federal Power Commission was represented by O. C. Merrill, the U. S. G. S. by N. C. Grover, chief hydrographer, and by W. E. King and W. E. Hall, division engineers. Col. H. B. Ferguson came from Washington as the personal representative of the Secretary of War.

Among the papers read, probably the most notable was that of O. C. Merrill on the subject: "Some Popular Fallacies Concerning Power Development." Mr. Merrill pointed out the fact that most of the controversies which are hindering the development of our resources and delaying the extension of utility service rest upon popular ignorance, which gives rise to fallacious opinions concerning the public utility business. Other papers of much interest were presented as follows: One by Maj. Harold G. Fiske, on "Methods Used in Surveying a Large River System;" one by Prof. Chas. E. Ferris, on "Possible Use of Large Crude Oil Engine Units for Stand-by Power Plants;" one by W. W. Ashe, upon the "Relation of Forest Cover to the Silting of Reservoirs."

During one evening the conference as entertained by a lantern slide address by F. G. Baum, in which he unfolded his scheme for a single national super-power system for the United States.

FEATURE OF CONVENTION

The outstanding feature of the convention was the adoption of the plan of reorganization presented by the executive committee. This plan contemplates the creation of three bureaus called the bureau of public relations, the bureau of industrial expansion, and the bureau of research. Believing that the scope of this organization is rather larger than its name implies, the conference voted to amend the name by dropping the word "water."

Among the resolutions adopted by the conference was one urging the Director of the Budget to recommend to Congress in its next budget that the original appropriation of \$2,000,000 for the purchase of forest lands on the headwaters of streams, as provided by the "Weeks Law" be restored, and that Congress be urged to restore this original appropriation. The Director of the Budget was further urged to consider the necessity for increasing the appropriation for co-operation with the states in forest fire prevention under the "Weeks Law" to at least \$1,000,000 a year.

Another resolution urges the importance of the extension of river navigation wherever possible by the building of navigation-power dams, particularly within the Appalachian South. Another resolution, addressed to the chambers of commerce and similar organizations of the section, calls attention to the fact that the early and full and effective development of water resources is being retarded by popular ignorance of the subject, resulting often in unwise legis-

Destructive Bridge Floor Fire

Largest Part of Six-Span Bridge at Stevens Point, Wis., Destroyed by Burning of Timber Floor

On May 30 a six-span bridge crossing the Wisconsin River at Stevens Point, Wis., was practically destroyed by fire. It was an old structure, having been built in 1877, and originally carried an ordinary timber floor. But within recent years, according to M. W. Torkelson, engineer-secretary of the Wisconsin Highway Commission, a new floor was placed, consisting of wood blocks on planks on modern stringers, all creosoted.

"The fire was first reported by tourists," Mr. Torkelson writes, "and when the city fire department arrived it had gained sufficient headway in the stringers under the floor to make it almost impossible to direct a stream of water against it. It seems that the fire spread very rapidly along the stringers underneath the floor, and while the upper portion still was prac-

tically intact, a very hot blaze was in progress underneath, and no headway could be made in fighting it until boats had been secured by which the fire could be attacked from beneath. The writer visited the bridge on June 1. At that time the two west spans of the bridge were completely wrecked and had collapsed into the river. The floor was almost completely burned off the two central spans, which were badly distorted by the heat. The upper portion of the floor of the two east spans was practically intact, but an examination of the stringers underneath the floor revealed that they were about two-thirds or three-fourths destroyed. The statement of the firemen who had assisted in fighting the fire was that water seemed to have very little if any effect."

To Straighten Chicago River

Plans for improving railway terminals and developing an industrial district by straightening the bend of the Chicago River between Polk and 17th Streets, have been advanced by the passage of a State bill which grants to

FIG. 1. WISCONSIN RIVER BRIDGE AT STEVENS POINT, WIS., AT HEIGHT OF FIRE, MAY 30

FIGS. 2 AND 3. EFFECT OF FIRE ON BRIDGE
At left, the two west spans which collapsed. At right, floorbeam damage in central spans.

lation and urging that a campaign be carried on for the true enlightenment of the public.

The incoming officers of the Southern Appalachian Power Conference are as follows: President, J. H. Wills, Atlanta, Ga.; vice-president, Col. Edgar Jadwin; secretary, J. A. Switzer, Knoxville, Tenn.; treasurer, Thorndike Saville, Chapel Hill, N. C.; chairman of the Executive Committee, Dr. Jos. Hyde Pratt, Chapel Hill, N. C.

the city the State's title to the present river bed, if the city provides a new channel. This bill was prepared because it had been held that in such a change the abandoned river bed would become the property of abutting landowners, so that the city would not be able to carry out the plans for the development of the new area by streets, terminal facilities and an industrial district as outlined in *Engineering News-Record*, May 19, 1921, page 845.

Railway Bridges Damaged in Two Unusual Fires

In One, Fire Starts in Cantilevered Roadway Under Bridge—In Other Oil Cars Burn in River

Two bridges of the Atchison, Topeka & Santa Fe Ry. were damaged by fire recently in unusual manner. The Mississippi River bridge at Fort Madison, Iowa, was damaged by burning of part of the highway deck cantilevered out from the railway portion, requiring difficult repairs which were carried out very rapidly. At Guthrie, Okla., a bridge over the Cimarron River was partly destroyed by gasoline and oil from wrecked tank cars which went into the river as the result of a derailment at the approach to the bridge. This same fire also wrecked a county highway bridge 600 or 700 ft. downstream. Details of the accidents as given by A. F. Robinson, bridge engineer of the system, follow.

The Fort Madison bridge, 2,960 ft. long, has about 1,000 ft. of pile structure with cross-tied ballast deck, at the east end. On either side of the railway deck is a wagon driveway, which in the trestle portion descends on a 4 per cent grade to the east until low enough to pass under the railway trestle, from which point it joins the south roadway. On May 24 fire was discovered in the sag of the roadway where it crosses under the railway deck. A strong wind prevailed, and when the fire was put out some 400 lin. ft. were burned and both wagon driveways from the middle of the east steel span to the east bank of the river. It is believed that the fire originated in trash which accumulated in the sag of the roadway, ignited by a cigar or match; it is known that the fire did not originate on the railway deck. The easterly span, 234 ft. long, had the cantilevered driveways and the timber deck burned for about half the span length. Two vertical posts of the downstream truss were badly crippled by heat and many of the jack stringers carrying the wagon driveways were so badly warped that they had to be replaced. This entire span was placed on falsework after the fire. Seventy-foot piles were required, the water being 45 ft. deep. By means of the gates of the Keokuk Dam the water was lowered 18 in. to prevent sawing over the piles and tapping them below permanent water level. A framed timber trestle was built on the caps. Railway traffic across the bridge was restored within four days after the fire, and in another week the wagon driveways were completed. Permanent repairs to the steelwork involved, besides minor work, cutting out about 3 ft. of the two vertical posts which were damaged, and splicing in new material. When this was completed the span was swung by releasing the wedges on the falsework, but it was watched for some time to detect any abnormal deflection as a result of the heating of the steelwork. No trouble of the kind developed however.

The Cimarron River bridge fire occurred on June 6. This bridge has two 210-ft. through truss spans at the north end, followed by four 80-ft. deck girder spans. A southbound freight train approaching the bridge had a car leave the rails, and the portion of the train behind this car did considerable damage to the northerly span in crossing. It knocked the southerly span off the piers

High Brick Wall Collapses in Wind Storm

During a severe wind and thunder storm which swept over Brooklyn, N. Y., during the afternoon of June 26, the whole central section of the northeast wall of the B. M. T. repair yards on Bushwick Parkway was blown over. In falling it crushed an automobile standing near the wall, killing one of the occupants and seriously injuring the other two. The portion of the wall blown over was approximately 240 ft. long and 24 ft. high. It was of brick, 12 in. thick, with 4-in. pilasters at about 10-ft. intervals. There also were two larger pilasters which had evidently been supports for machinery or roof trusses in some structure no longer in existence. Otherwise the wall was unsupported. There were three or four window openings in the wall and one large door opening. An examination of the portion of the wall still standing indicates that the central portion in falling started to rotate about the top of the foundation wall, opening a crack along the inside of the wall at that point, but finally failed along the line of the window sills, falling outward across the sidewalk and well out into the street.

Order Against Chicago Sanitary District Entered

A formal order against the diversion from Lake Michigan of more than 4,167 sec.-ft. (250,000 min.-ft.) of water was entered on June 20 by Judge Carpenter of the federal district court against the Sanitary District of Chicago but the district was given six months to appeal the case to the Supreme Court. The suit was started in 1908. In 1914 the case was tried before Judge K. M. Landis, who did not announce his decision until 1920. Even then he merely handed down an oral decision, with a statement that to give the district a chance to appeal to the War Department for relief he would not put the decision into effect. On the retirement of Judge Landis from the bench without having issued an order the case went to Judge Carpenter, who has been over the testimony and arguments with the result indicated. The oral opinion by Judge Landis, a summary of the case, and a statement of the viewpoint of the Sanitary District officials, appeared in *Engineering News-Record*, July 15, 1920, p. 129; editorial comment was made on p. 99 of the same issue.

and into the water, and eighteen cars of oil went down. Oil and gasoline in the river took fire. Subsequent inspection showed the south span to be a total loss while the north span was so much damaged as to make it uneconomical to attempt to reuse such of the old material as could be repaired. Besides these two spans, the pier between them had its limestone shafts so completely damaged by the heat that it will have to be rebuilt above the water line. In reconstruction, pneumatic piers will be sunk in the middle of the two truss span openings, and 106-ft. girders spans will be placed. Temporarily traffic is being taken care of by a pile bridge upstream of the present bridge, the full length of the crossing. The new bridge is to be built during the present year.

Proposed Power Projects Cover Wide Area

Ford Interests Busy on High Dam Plans—Developments Planned in Pennsylvania and the Carolinas

Every effort is being made to push the completion of the plans and the granting of the license for Ford's new dam on the Mississippi at St. Paul. It is probable that the Federal Power Commission will so word the permit as to allow Mr. Ford to erect a steam plant immediately adjacent to the hydro plant. His original plan of having the steam plant in the same building and directly over the hydro plant was abandoned due to the possibility of foundation trouble. The Ford interests are attempting to have the Federal Power Commission reduce the interest rate on the value of the dam from 5 per cent to 4 per cent. The figure 5 per cent was made to conform with that applied to the dam at Troy, which is under a similar lease to Mr. Ford. At present the annual fixed charge is set at \$95,000, an amount made up of 5 per cent interest on the value of the structures, which is \$1,200,000, 1½ per cent maintenance, and 1½ per cent depreciation.

The Pennsylvania Power & Light Co., a subsidiary of the Electric Bond & Share Co., has made application for a license to develop 47,000 kw. on the Wallenpaupack River near Scranton, Pa. They also propose to construct a reservoir with a storage capacity of 9,000,000,000 ft. As the Wallenpaupack is a tributary of the Delaware, the construction of this large storage reservoir will have a considerable effect upon the proposed development along that river. The latter developments are being held up on account of the fact that New York, Pennsylvania, and New Jersey, having jurisdiction over different sections of the Delaware River, have not been able to agree on their hydro-electric power plans.

Plans for the diversion of the Santee River through a 15-mile canal to the upper reaches of the Cooper River near Moncks Corner are being prepared by the Columbia Railway & Navigation Co. The initial installation will be between 30,000 and 50,000 hp. and will call for a dam which will raise the head to 55 ft. Future installations call for a dike and a higher dam which will raise the head to 70 ft. and permit an installation of 150,000 hp. The feasibility of the project has been enhanced by the progress of the construction of hydro-electric plants and storage reservoirs on the upper tributaries of the Santee, which have raised the low flow of the Santee River from 3,000 to 10,000 cu. ft. per second. The only adverse circumstance affecting the development is the requirement of the War Department that sufficient water pass the dam to maintain navigation on the Santee River.

Contract Let for \$6,000,000 Railroad Line in Mexico

For the construction of an 85-mile single-track railroad between La Quemada and Tepic, Mexico the Southern Pacific Railroad has awarded to the Utah Construction Co. a contract amounting to about \$6,000,000. This line will give the Southern Pacific an entrance into Mexico City in connection with the National Railways.

Golden Gate Bridge Discussed in San Francisco

At a well attended meeting in the city hall at San Francisco, called to consider the question of bridging the Golden Gate, M. M. O'Shaughnessy, city engineer, explained details of a combined cantilever and suspension bridge for which he had made the foundation explorations, and the superstructure design of which was prepared by J. B. Strauss. This bridge would have a center span of 4,010 ft. with two 1,345-ft. approach spans. The bottom chord would be about 200 ft. above water level and the top chord over the piers would be about 780 ft. above water level. The structure would be designed to carry 30-ton electric cars and the roadway would be 52 ft. wide between curbs. The two piers would be founded on bedrock in 50 ft. of water. The cost of the structure complete with the necessary highway approaches Mr. O'Shaughnessy estimated at \$25,000,000.

Other bridges, proposed by Capt. John G. Little as alternative types and estimated to cost \$11,000,000 and \$14,000,000 respectively, would involve a combination trestle-and-tube structure or a high-level bridge with three 1,100-ft. spans. Either of these structures would be some distance inside the Gate proper, where the water is not nearly so deep, and each would have a length of about four miles. The high bridge would clear the water by 200 ft. and in the other type, the tube, would afford a 1,500 or 2,000-ft., unobstructed channel of a 50-ft. depth.

Details of the enabling act (Assembly bill 1288) passed by the recent legislature authorizing counties to join in assessing a tax levy and issuing bonds for the bridge were explained. Before adjournment, the meeting passed resolutions directed toward petitioning for a hearing before the War Department to determine whether permission for the proposed crossing could be secured.

Bids for Laying Los Angeles Sewer Outlet in Ocean Wanted

Bids for laying 5,184 ft. of 84-in. pipe extending into the Pacific Ocean to a water depth of about 50 ft. and for two 60-in. branches each 283 ft. long ending in some 56 ft. of water, laid at angles of 45 deg. from the 84-in. pipe, are to be received by the Board of Public Works of Los Angeles, Calif., up to 10 a.m. July 30. The pipe will be supplied by the city of Los Angeles at the Hyperion railway siding, free of charge to the pipe-laying contractor. This work constitutes the ocean outlet of the new North Outfall sewer shown on a map printed in *Engineering News-Record*, June 7, p. 1,000.

Alternative bids are invited for Class D standard bell-and-spigot cast-iron pipe and for submarine reinforced-concrete pipe having a special bell-and-spigot joint. The pipe will be laid just below the ocean bottom which has a slope of about 1 per cent from the high-tide line outward. Borings indicate that the bottom consists almost wholly of sand. Piling is required for a distance of 700 ft. through the surf and concrete aprons must be laid around each of the two special outlet fittings, which latter will discharge upwards at a level about 4 ft. above the ocean bottom. John A. Griffin is city engineer and W. T. Knowlton is engineer of sewers.

Washington Award Conferred on Capt. Robert W. Hunt

The Washington Award for 1922, for "pre-eminent services in promoting the public welfare" has been awarded by the Western Society of Engineers to Capt. Robert W. Hunt, Chicago, and the presentation of the heavy bronze tablet mounted on a marble slab was made at the annual dinner of the Society, June 18. The award was

founded in 1916 by John W. Alvord and the recipient is selected annually by a commission representing the Western Society and the four national societies of civil, mechanical, mining and electrical engineers. This distinction is conferred upon Captain Hunt, "for his pioneer work in the development of the steel industry in the United States and for a life devoted to the advancement of the engineering profession."

C. E. Ashburner City Manager of Stockton at \$20,000

Charles E. Ashburner, city manager of Norfolk, Va., will become city manager of Stockton, Calif., Sept. 1 at a salary of \$20,000 a year, a \$4,000 advance over his present salary. Mr. Ashburner is the pioneer city manager of the country, having served as general manager of Staunton, Va., from April, 1908, to July, 1911; and city manager of Springfield, Ohio, from 1914 until he went to Norfolk in the same capacity in 1918. From 1911 to 1914 he was with the American Railways at Lynchburg, Va. Stockton adopted the commissioner-manager plan recently, to go into effect July 1. The population of the city in 1920 was 40,296 against 23,253 in 1910 and 17,506 in 1900. The Staunton general manager plan, which antedated by several years the city manager plan, was described in *Engineering News*, July 8, 1909, p. 32.

Plan Another Rail Line in Mexico

The National Railways of Mexico is contemplating the construction of a 30-mile line southeast from Mexicali, which is on the California-Mexican line in the Imperial Valley, to San Felipe on the Gulf of California, according to an announcement made in San Francisco by J. M. Carpio, assistant director general of the National Railways.

Engineering Societies

Calendar

Annual Meetings

AMERICAN SOCIETY OF CIVIL ENGINEERS, New York, Annual Convention, Chicago, July 11-13.
NEW ENGLAND WATER WORKS ASSOCIATION, Boston, Mass.; Annual Convention, Burlington, Vt., Sept. 18-21, 1923.
AMERICAN PUBLIC HEALTH ASSOCIATION, New York; Annual Meeting, Boston, Oct. 8-11.

The Rochester, N. Y., Engineering Society elected the following officers at its annual meeting June 8: Waldo G. Wilds, president; Stephen B. Storey and Gloster P. Hevenor, vice-presidents; Walter S. Burch, secretary; and Leonard A. Waasdorp, treasurer.

The Engineers' Society of Pennsylvania at its meeting June 11 installed its officers for the coming year, as follows: Robert W. Moorhead, president; R. L. Gillespie and Charles Haydock, vice-presidents; Howard E. Moses, secretary; and Paul E. Fickenschner, treasurer.

The Engineers' Club of Baltimore is co-operating with a committee on efficiency and economy which has been appointed by Mayor Howard W. Jackson to suggest plans for the reorganization of city departments. Ezra B. Whitman, a member of the Public Service Commission of Maryland, and an engineer, is chairman of the committee named by the Mayor. He has asked Engineers' Club members for suggestions. The club has sent out postals to all its members asking that they make practical suggestions for improvement in the various city departments.

The Dayton, Ohio, Engineers' Club recently elected president Charles H. Paul, chief engineer of the Miami Conservancy District. The vice-presidents are: John H. Hunt, O. B. Reemelin, and C. D. Putnam; J. C. Matthieu is secretary, and Fred L. Kohnle is treasurer.

Personal Notes

L. A. BOULAY, of L. A. Boulay Co., civil and sanitary engineers, Toledo, Ohio, assumed office July 1 as director of highways and public works for the state of Ohio, succeeding Leon C. Herrick. Mr. Boulay, who has lived in Ohio seventeen years, was first deputy engineer in the office of the Lucas County surveyor and later sanitary engineer for Lucas County, after which he organized his own company. His previous service had been varied. He served as civil engineer for the U. S. General Land Office in Utah and in Arizona. As chief engineer Mr. Boulay had charge of the construction of the Benguet R.R., a 40-mile electric line in the Philippines. He was an engineer for the Canton-Hankow R.R. in China, and constructed a 20-mile railroad in Mexico for the Pan

American Co. of New York. For a short time he was an engineer for the District of Columbia on grade crossing elimination and building of the new Washington depot. He was also engineer in charge of construction of the Holguin branch and of the San Luis Potosi railroads in Cuba.

T. C. DESMOND & Co., Inc., general contractors, have moved their offices to 247 Park Avenue, New York City, the building being a new twenty-story office building just completed by this company.

SALISBURY & BRADSHAW, consulting engineers, Los Angeles, Calif., announce the association with their firm of ARTHUR TAYLOR, under the firm name of Salisbury, Bradshaw & Taylor. Mr. Taylor has been associated with Mr. Salisbury for many years on several irrigation and development projects, and the three members headed the engineering and construction staff on the Lake Arrowhead project in 1921 and 1922.

GEORGE W. CRAIG, formerly city engineer of Calgary, Alta., has been appointed district engineer for the Asphalt Association, with offices in Chicago, instead of the Portland Cement Association as stated in these columns June 14.

H. A. NOBLE, formerly assistant engineer on irrigation work with the Valier Montana Land & Water Co., Valier, Mont., has joined the force of H. M. Bylesby Engineering and Management Corp., Chicago, as draftsman for concrete and steel.

E. L. CHANDLER, who formerly was division engineer with the Miami Conservancy District on channel improvement work, is now engineer in dam construction in Iowa for Price Brothers Co., contractors, Dayton, Ohio.

M. N. YANCEY has been appointed engineer on construction for the Florida State Road Department. Mr. Yancey was formerly superintendent of bridge construction for the Talbert construction Co.

LT. WILLIAM S. KILMER, U.S.A., has been transferred from the Field Artillery to the Corps of Engineers. LT. HUBERT S. MILLER and LT. EDWARD H. COE have been transferred to the Corps of Engineers from the Infantry. LT. EUGENE L. VIDAL has been transferred from the Corps of Engineers to the Air Service and LT. FRED W. MARLOW and LT. THEODORE T. KNAPPEN have resigned from the army.

ANDREW J. PROVOST, JR., consulting engineer, 39 West 38th St., New York City, has been elected chairman of Committee C-4, American Society for Testing Materials, on clay and cement sewer pipe, to succeed Dr. Rudolph Hering, who, at the time of his recent death, had served as chairman for eighteen years.

J. J. ROSEDALE has resigned from the position of chief construction engineer, Department of Safety, California Industrial Accident Commission, and has opened an office in the Sharon Building, San Francisco, as representative of manufacturers of safety and sanitary devices and fire prevention equipment.

MAJOR DONALD H. CONNOLLY, of the Corps of Engineers, has been ordered to Memphis.

MAJOR MILO P. FOX has been ordered to Washington to serve as assistant to Brig. Gen. Harry Taylor. He succeeds Lieut. Col. George D. Pillsbury, who will take a course at the engineer school.

Dr. ELLSWORTH HUNTINGTON has been appointed delegate of Yale University to the Pan-Pacific Scientific Congress to be held in Australia during the summer. Dr. Huntington is the author of "Climatic Changes," "Civilization and Climate," and of a new book, "The Earth and the Sun," which is to appear this fall.

CHARLES G. YALE, who recently retired from active charge of the San Francisco office of the U. S. Geological Survey, was the guest of honor at a banquet given by the San Francisco Section of the American Institute of Mining and Metallurgical Engineers. Mr. Yale had been forty years in the survey office.

W. G. EAGER has been appointed consulting and supervising engineer at Valdosta, Ga., to take charge of the construction of new waterworks planned for that city.

CHARLES LYBROOK, Logansport, Ind., former county surveyor, has been named city engineer to succeed John Paul Davis whose resignation went into effect June 1.

PAUL HAMILTON has been appointed assistant chief engineer of the Cleveland, Cincinnati, Chicago & St. Louis, W. C. KEGLER has been made engineer, track and roadway, of the same road, E. H. MCGOVERN and J. E. KISSEL engineers, maintenance-of-way, and W. B. HODGE office engineer.

JAS. A. OGDEN, rancher and oil operator of Kern County, has been named city manager of Bakersfield, Calif.

W. E. WHALIN, building contractor, has been appointed to succeed Wilfred N. Ball, resigned, as superintendent of construction for the Oakland, Calif., Board of Education.

FRED B. COLE and H. F. KIMBALL, for many years with Charles T. Main, Boston, Mass., and H. E. Osgood, recently representative of the Sanford Riley Stoker Co., have formed a partnership, Cole, Osgood & Kimball, Boston, Mass., to do general engineering work and specialize in power plants, textile and industrial lines.

C. C. CARPENTER has resigned as professor of civil engineering at Ohio Northern University and will devote all his time to structural work, specializing in highway bridges.

HOWARD S. REED has resigned as city engineer at Phoenix, Ariz., and Henry Rieger, assistant city engineer, has been appointed to the position temporarily.

L. C. FRITCH, vice-president of the Chicago, Rock Island & Pacific Ry., has been appointed vice-president and general manager, succeeding T. H. Beacom, resigned.

J. O'NEILL has resigned from the staff of the St. Lawrence Paper Mills at Three Rivers, Quebec, to accept a position with the Thompson-Starrett Co., New Haven, Conn. Mr. O'Neill attended the University of New Brunswick. He has been city engineer of Fredericton, N. B., and assistant engineer with the Henepin Bridge Co., Minneapolis.

W. G. FOWLER has been appointed bridge designer and draftsman with the Missouri State Highway Commission; he previously held a similar position with Heyl & Patterson, Inc., Pittsburgh, Pa.

Obituary

DR. HERMAN M. BIGGS, commissioner of health of the state of New York since 1914, previously known the world over for his bacteriological and pathological work in the field of public health, died in New York City on June 28. He was born at Trumansburg, N. Y., in 1859; graduated from Cornell University and Bellevue Hospital Medical College with the degrees of A.B. and M.D., and continued his studies abroad. From 1892 to 1901 he was pathologist and director of the bacteriological laboratory and from 1901 to 1914 was general medical officer of health of the New York City Health Department.

DR. C. LINCOLN FURBUSH, director of the Department of Health of Philadelphia since 1919 died on June 26. He was born in New York City in 1863. From 1898 to 1902 he was in the medical service of the United States Army. He also served in various capacities during the World War as a colonel in the Medical Corps, U.S.A.

HUGH DOHENY, contractor, president of Hugh Doheny & Co., Ltd., and vice-president of the Canada & Gulf Terminal R.R., died recently at the age of 59. Mr. Doheny was one of the well-known railway builders in Canada. He had built many lines including sections of the Canadian Pacific R.R., the Soo line, the New Hampshire R.R., sections of the Quebec Central, the Sault Ste. Marie Canal, lines in Cape Breton, part of the Temiskaming and Northern Ontario R.R., and many others.

FRANK W. BROOKS, who retired two years ago from the presidency of the Detroit United Rys., died June 28 after a long illness. He was born in Texas in 1864 and his early railroad work was in the engineering department of the Texas & Pacific R.R.

BRIG. GEN. LEWIS T. BRYANT, New Jersey state commissioner of labor, and a graduate civil engineer, died June 27 in Trenton, N. J., aged 49 years. General Bryant was born in Atlantic County, N. J., graduated from the civil engineering department of Pennsylvania Military College at Chester, Pa., and was mustered into the United States Volunteer Army in 1898, being advanced within a few years to brigadier-general. In 1904 he was appointed inspector of factories and workshops for the state of New Jersey, and the title was changed that year to commissioner of labor, General Bryant receiving appointments by succeeding governors that carried his term to the present time.

W. A. CAMPBELL, reclamation engineer, died at Jacumba, Calif., June 20. Mr. Campbell was a graduate of the University of Pennsylvania and in 1908 was employed in the construction of Laguna Dam; for several years he was identified with engineering work in the lower Colorado district and for the last five years has been on the Imperial irrigation district engineering staff.

A Point of Contact
Between Maker and User of
Construction Equipment and Materials

Concrete Mixer Conference Discusses Standards

Manufacturers and Contractors Consider Limiting Building Mixers to Four Sizes and Pavers to Three Sizes

Engineering News-Record Staff Report

TO FURTHER the movement for standardizing construction machinery in the interests of economy and efficiency for both contractor and manufacturer a meeting of concrete mixer manufacturers, contractors and engineers was held in Chicago, June 27 to 29, under the auspices of the Associated General Contractors of America. It was agreed, pending final ratification, to limit building mixers to four sizes and paving mixers to three sizes. A uniform method of measuring and rating mixer drums was approved and standards were fixed for the capacities of water tanks on mixers of various sizes.

In explanation, it may be said that as a result of a conference of construction equipment manufacturers and the Associated General Contractors in January, a standardization steering committee of contractors and mechanical engineers was appointed to arrange discussion with the manufacturers of such equipment as appeared capable of some standardization and to formulate with them a program for carrying on the work. The next step was at a meeting of this committee and a number of concrete mixer manufacturers held in Cleveland, May 21, when an outline was drawn up of the various factors requiring consideration. This outline was then submitted to mixer manufacturers throughout the country with a request that they attend a general meeting for the purpose of making recommendations.

MEASUREMENT AND RATING

At the Chicago meeting this outline was discussed, and comments, prepared in advance by contractors and a committee of mixer manufacturers, were also submitted. Some of the principal points of discussion are noted below:

1. *Standards of Measurement*—As amended in discussion, the report provides that the standard of measurement of drum capacity shall be a cubic foot of water at 60 deg. F.; that tank capacity shall be measured by the U. S. gallon; that boilers, steam engines and gas engines shall be based on the rating of the American Society of Mechanical Engineers, and electric power apparatus on the ratings of the American Institute of Electrical Engineers.

2. *Method of Measuring Drum*—The steering committee stated that there is a question among manufacturers as to whether measurement should be made with the drum rotating or at rest and whether it is wise to include the carrying capacity of the pick-up buckets, which is available while mixer is in operation.

Both the manufacturers and the contractors agreed that the drum should

be at rest and the contractors' statement included the further remarks that the drum should be absolutely level, that the loading device should not be the unit of measurement and that the capacity of the pick-up buckets should not be included, as it is too indefinite and is not easily measured in the field by the purchaser. The conclusion, as adopted after discussion, was that: "The water level capacity of the drum standing still shall be used as the capacity of the drum."

3. *Rating of Drum*—Four types of drums were listed by the steering committee: (A) horizontal drums with

Lubrication of Equipment

On account of the space needed in this department this week for the report on the concrete mixer conference it is necessary to postpone until next week the second installment of the article, "The Lubrication of Construction Equipment," which began in the June 28 issue, p. 1144.—EDITOR.

opening at both ends; (B) same as (A) but with discharge opening closed during mixing action; (C) tilting drum with vertical axis and single opening; (D) tilting drum with horizontal axis and double opening. The contractors' statement remarked that: "The capacity of mixer drums as given in catalogs is sometimes not dependable. Different makes of mixers with the same rating, handle quite different quantities of material. It would seem, therefore, that mixers of the same type should have the same diameter, same speed, same size of openings and same number of buckets with the same nitch."

As to class A, or non-tilting mixers, it was concluded that for both building and paving mixers the water level capacity of single-opening drums should be approximately, but not more than 107 per cent of, the nominal capacity or rating; and approximately 50 per cent for double-opening drums. Consideration of tilting drums in classes C and D was referred back to the committee of the manufacturers association, as this type of mixer was not represented. Another conclusion adopted was: "The maximum operating grade to be considered in the rating of paving mixers is 5 per cent."

4. *Table of Aggregate Proportions*—The steering committee proposes to gather information as to the volume of wet concrete produced from various proportions of batches with varying

water content and varying voids in the aggregate. The manufacturers' association proposed that a new table be prepared, utilizing the data in the tables of Abrams, Taylor and Thompson, this table to indicate specifically the quantity of water to be considered in rating mixers, together with the voids in the aggregate used. After some discussion this subject was referred back to the steering committee, and was afterwards adopted substantially as above.

5. *Standard Sizes of Mixers*—Protracted discussion from varied points of view followed the presentation of the subject of standard sizes. The advantages to both manufacturer and contractor which will result from the reduction in sizes of mixers was pointed out, but there was evidently much doubt as to two particular points: (1) Whether some manufacturers might seek to retain certain individual advantages by making sizes other than standard; and (2) whether the number and sizes of standard mixers would satisfy the contractors. One maker stated that a certain size proposed to be excluded is one of his best sellers, but he would sacrifice it if assured that no other manufacturer would continue to produce that size. Another maker thought that the contractors are the best judges of what contractors want and will demand, and he would not accept any list of standard sizes unless it was approved by the contractors.

SEVEN SIZES APPROVED

It was suggested that for general and building work there should be four sizes: Nos. 4, 7, 14 and 28. But there was wide diversity of opinion as to whether four sizes are sufficient and what these sizes should be. The question of mix came up and it was pointed out that it is very desirable to avoid sizes which would require a half-sack of cement to complete the batch.

A limit of four sizes of mixers for general and building work was approved, but discussion developed some objection to No. 4 and preference for No. 5, so that eventually it was decided to refer the selection of the smallest size to a committee of manufacturers. The possibility of adopting No. 21 as a fifth size was also considered. For paving mixers, two sizes were suggested originally: No. 21 and another approximately half that size. The final action, however, was the adoption of three sizes: No. 7, No. 12 and No. 21.

6. *Measuring Drum Speed*—The suggestion was made that for single-opening drums peripheral speed is preferable to revolutions per minute and that this speed should be measured at the center of mass of the batch. Both speeds to be given by the manufacturer. Finally this was referred back for further consideration.

7. *Water Tanks*—Tanks are to be rated on the amount of water discharged per batch and are to be of the following capacities for standard size of mixers: No. 7, 12 gal., with 2-in. hose nipple for water supply connection; No. 14, 22 gal. with 1½-in. pipe; No. 21, 32 gal., with 1½-in. pipe, and No. 28, 42 gal., with 2-in. pipe connection.

Numerous other subjects which were discussed more briefly and will be covered by the final report included the following:

Building Mixers: Sizes to which

Contractors Deny Padded Estimates for Cement

Tell Hoover That Manufacturers Dodge Responsibility for Deliveries in Present Form of Contract

ADENIAL of the accusations, made by cement manufacturers, that contractors over-estimate requirements and duplicate orders for cement for purposes of speculation is made in a letter to Secretary of Commerce Hoover, dated June 25, from J. W. Cowper, president, and other members of the Associated General Contractors of America. The communication is in answer to an earlier letter (dated April 9) received by the Secretary of Commerce from six cement manufacturers (Atlas, Hercules, Penn Allen, Dexter, Lehigh and Alpha). To the statement made by the cement companies that 40 per cent of the cement contracted for on engineering and construction work in 1920 was not required, the contractors reply that this estimate is excessive and that over-ordering during the year did not exceed 10 per cent of production.

The cement manufacturers' letter begins with an explanation of its "specific job contract" under the terms of which the manufacturer agrees to deliver the cement required during the entire construction period of the project at an agreed price. These contracts, the manufacturers state, are made to minimize speculation to the detriment of the public. Padded contracts for cement, it is claimed, are common practice among purchasers, as are also duplicate orders on different manufacturers. This year, the letter states, there is no doubt of an outstanding duplication or padding of contracts for cement running into many million barrels that will not be called for delivery. If it were possible to eliminate them, it is pointed out, this additional amount of cement would be available for sale. This year, cement production is estimated at 125,000,000 bbl. The cement manufacturers close their case with pleas for avoidance of duplicated orders, for limiting estimates for cement to actual needs, and for spreading purchases throughout the year.

CONTRACTORS REPLY

In their reply the contractors admit that over-ordering or duplicating of orders does occur to a very limited extent, but not as a means of speculation.

(Concluded from p. 36)

power discharge, extension loaders and rubber tires may be applied. Discharge control from one or both sides. Open or closed ends for skips. Size of skip and rating by heaped load or level load. Standards for wheels will be referred to wheel manufacturers.

Paving Mixers: Sizes to which caterpillar equipment may be applied. Width of skip. Hand or power steering and boom swing. Forward and reverse speeds.

General: Drum gearing. Quality of material. Safety devices. Standardizing of motive power. Standard names for parts. Name plates showing standard rating.

On the basis of the extensive discussion during the three-day meeting the proposed rules for standardization will be revised and submitted for approval.

Cement, the contractors assert, is almost universally sold under a loose form of contract which guarantees the price but which does not bind the seller to deliver a given quantity of material within a given time, a matter of vital importance on highly organized construction work, notably highways. "If the manufacturer and the dealer, who receives a commission on all cement used in his territory, will assume responsibility for delivery at a given time," the letter from the contractors states, "the practice of over-ordering or duplicating can doubtless be eliminated. It has its birth in the trade practices of cement selling, and upon revision of these practices depends its correction. Since the manufacturer does not agree to deliver at a given time or rate, and since the owner demands his project at a given time, the construction company is obliged to accept responsibility for contingencies which neither of these will assume."

The construction companies, it is claimed, are frequently injured by the form of contract insisted upon by the cement manufacturers and have sought its abandonment in favor of a bona fide mutual non-cancellable contract, guaranteeing delivery and acceptance, and relieving the seller from delays of transportation. This offer, it is stated, has been declined by the cement producers.

The general tone to the cement manufacturers' letter and its date lead the contractors to infer that it was conceived in opposition to a construction conference. The contractors' communication to Secretary Hoover concludes with the statement that "the trade association is casting aside many features of the competitive system and has reached that stage of group co-operation where the principal evils of the competitive plan still survive, but where the public has not derived its share of benefit from the co-operation." Industries, the contractors believe, must exercise proper government of themselves. If this course is not followed voluntarily they predict that "it will doubtless be followed under the distasteful pressure of law."

Business Notes

GRAHAM B. BRIGHT Co., Richmond, Va., has been appointed Virginia representative for the T. L. Smith Co., Milwaukee, manufacturer of concrete mixers, pavers, excavators and loaders.

C. E. ROWLEY has resigned as advertising manager of the *Novo Engine Co.*, Lansing, Mich., and is succeeded by **R. P. Ostrander.**

B. L. G. REES, who joined the business staff of *Engineering News-Record* Feb. 2, has resigned, effective July 1, to become New England advertising manager of *The Nation's Business*, the monthly publication of the Chamber of Commerce of the United States. He will cover the New England and half of the New York territory, with headquarters in New York City.

EDWARD W. BUCKLEY has been appointed by the Mayor to the newly created position of Commissioner of Purchase of the City of New York, effective July 1. He was formerly deputy state tax commissioner.

Equipment and Materials

Electric Capstan Car Puller

A new product of the Gifford-Wood Co., Hudson, N. Y., is an electric capstan car puller for use in spotting freight cars to be loaded or unloaded on sidings at industrial plants. The equipment is inclosed by cast-iron housing and consists of a 5-hp., 1200-r.p.m. electric motor operating the capstan head through either gear or belt drive. The base is held down by five bolts

and occupies an area of 2 ft. 8 in. by 2 ft. 9 in. The housing is split and bolted together so that the upper section, with capstan and bevel gear, may be lifted off to expose all working parts. The equipment produces a rope speed of 44 ft. per minute and a pull on the rope of 2,630 lb. The capstan will pull two loaded cars of 75 tons weight or seven empties of 25 tons each on level track. The device is operated by simply hooking the rope onto the freight car to be pulled, giving it a few turns around the capstan head and throwing the motor switch.

¾-Yd. Revolving Shovel Operates With Only One Motor

Only one motor, gasoline or electric, for all operations is a feature of the design of the ¾-yd. revolving, crawler-mounted shovel developed recently by the Northwest Engineering Co., Chicago. The new design involves a form of cable control that eliminates auxiliary engines and reduces the number of racks, gears, and pinions ordinarily required on equipment of this type. Where a gasoline engine is used the power unit is a four-cylinder machine

developing 57 h.p. at 800 r.p.m. In the case of electric power a 40-hp. squirrel-cage type motor drives the first reduction gear through a full universal joint, thus relieving the motor bearings of any loads due to disalignment resulting from wear or other causes.

A patented dipper control, by cables, makes possible a simple electrical installation. Current is delivered to the travel base through suitable plug-in connections and is transmitted to the

rotating base by means of a set of large collector rings, all wiring being in conduits.

The weight of the shovel, complete, is 53,000 lb., the length of boom between centers 23 ft., and length of dipper stick 14 ft. 3 in. The crowding motion is controlled by cables from the same drums as are used in clamshell or dragline work. The operation of crowding has no effect in reducing the net available digging force which, the manufacturer claims, is the case with crowding mechanism operated by chains or gears.

In the design of the crawler traction the double flanged rollers which ride on the crawler track are of manganese steel and run on 23-in. pins of chrome-manganese alloy steel. This combination of metals, the manufacturer states, eliminates the objection of using bronze bushings at this point, for the manganese roller will not freeze to the pin even if lubrication is neglected. The final drive to the crawlers is through a roller chain and socket which is said to be superior to gears on account of the grit and mud usually present in the operation of a power shovel.

The power shovel equipment is interchangeable for operation as a clamshell bucket, dragline, pilerdriver hammer, lift magnet, or trench hoe.

Concrete Mixers of Record Size Shipped to Canada

T. L. Smith Co., Milwaukee, has just shipped to Hebertsville, Canada, two 4-yd. (112-S) tilting mixers for use on the dam and hydroelectric project at Hebertsville. These mixers are duplicates of the two that were used at the Muscle Shoals project in Alabama and are claimed by the company to be twice as large as any other concrete mixers ever built.

Four 56-S (2-yd.) mixers of this same type are now being built for use on the Wilson Dam project across the Tennessee River, at the foot of Muscle Shoals, on which two of the Smith 4-yd. and two 2-yd. tilting mixers were formerly used.

Publications from the Construction Industry

Road Rollers—HUBER MANUFACTURING Co., Marion, Ohio, features in a 16-p. pamphlet its motor road roller operated by four-cylinder, 50-hp. gasoline engine. The roller has one front and two rear rolls and weighs 20,000 lb. It can be used also as a tractor for pulling road graders.

Welded Pipe Joints—OXWELD ACETYLENE Co., Newark, N. J., has published a 40-p. illustrated booklet containing reprints of articles dealing with the use of welded joints instead of threaded or coupled joints for pipe lines. The ground covered is largely in the oil and gas fields.

Turbines—KERR TURBINE Co., Wells-ville, N. Y., has issued an illustrated bulletin describing its plant for the manufacture of steam turbines and gears. The bulletin, which contains 12 p., is the first of a series which will tell the story of the various sizes and types of turbine built by the company in the same way that the present bulletin describes the company's plant.

Business Side of Construction

FACTS AND EVENTS THAT AFFECT COST AND VOLUME

Lumber Production Steady

The national lumber movement, as observed by the National Lumber Manufacturers Association, declined quite noticeably during the week June 3-9 as compared with the preceding week, though allowance should be made for the fact that reports were received from 26 fewer mills. Production is still much in excess of what it was at this time last year, and is more than normal; shipments are about the same and new business about 15 per cent less.

For all the 396 reporting mills shipments were 89 per cent and orders 70 per cent of production. The corresponding percentages for the Southern pine group were 90 and 69, and for the West Coast 100 and 88. The 359 of the reporting mills that have a normal production figure for the week show actual production to have been 108 per cent of normal, shipments 100 per cent of the same, and orders 80 per cent. Unfilled orders of 133 Southern pine mills are 12,298 cars, equivalent to 261,959,698 ft., a reduction of about 40,000,000 ft. from the previous week. Unfilled orders of the West Coast Lumbermen's Association mills are given as 250,608,857 ft. of cargo business and 7,365 cars of rail trade business.

The following table summarizes the lumber movement for the week, June 3-9, the corresponding week of 1922 and the preceding week of 1923:

	Prod- Week	Correspond- ing Week 1922	Preceding Week 1923 (Revised)
Mills.....	396	379	422
Production.....	265,825,535	228,007,506	281,343,261
Shipments.....	235,495,386	231,926,304	268,747,524
Orders.....	186,025,245	220,878,037	208,077,032

The following figures compare the lumber movement so far this year with the same part of last year:

	Production, Ft.	Shipments, Ft.	Orders, Ft.
1923.....	5,512,486,896	5,925,685,551	5,933,893,770
1922.....	4,331,450,101	4,640,944,156	5,060,336,049
1923 In- crease	981,036,795	1,284,741,395	873,557,721

Production of Paving Brick

Production of No. 1 paving brick during May, according to the monthly report of the National Paving Brick Manufacturers Association, Cleveland, based on returns from 24 companies, totaled 34,382,000 brick, a slight gain over the April figures. Shipments in May amounted to 26,209,000, while stocks on hand at the end of the month were 77,662,000 brick. Unfilled orders aggregated 96,752,000 brick.

Pig Iron Production in May

Pig-iron production in May, according to figures received by the Department of Commerce, amounted to 3,868,000 tons, as against 2,307,000 tons in May a year ago. Production of merchant pig iron totaled 600,000 tons, as against 250,000 tons in May, 1922. Steel-ingot production, allowing for companies not reporting, amounted to 4,205,000 tons, as compared with 3,948,000 in April and 3,223,000 tons in May of last year.

Building Cost Index Higher

The index, for May, of the cost of building materials entering into the construction of a six-room brick house, as compiled by the Department of Commerce, stood at 214, on a 1913 base, as compared with 209 in April and 176 in May a year ago. Production of oak flooring in May amounted to 34,636,000 ft., as compared with 21,914,000 ft. in May a year ago. Cement production in May amounted to 12,910,000 bbl. and shipments totaled 14,257,000 bbl. for the month. The estimated total bookings for fabricated structural steel in May amounted to 145,000 tons, as against 202,500 a year ago.

Malleable Castings

The Department of Commerce announces 61,950 tons as the total production of malleable castings manufactured for sale during the month of May, 1923, as shown by reports received by the Bureau of the Census. The returns include only those castings manufactured for sale as such and does not include those used in the plants or finished and sold as other products. The returns include the production of 85 establishments and show that these plants were operated at 70.9 per cent of their total capacity during the month of May. Total shipments for the month were 60,221 tons; orders booked were 49,730 tons; and monthly plant capacity was 87,419 tons.

Large Contracts Let During Week

Among the week's announcements of contracts awarded in Construction News, pp. 1 to 10, are the following: Tunnel, New York, N. Y., to Rodgers & Hagerty, Inc., \$3,467,414. School, New York, N. Y., for Board of Education, \$1,185,000.

Packing plant, Denver, Col., to C. S. Lambie, \$1,000,000.

Commercial building, Pittsburgh, Pa., to Dwight P. Robinson Co., Inc., New York, N. Y., \$1,000,000.

Cement mill, Manitowoc, Wis., to MacDonald Eng. Co., Chicago, Ill., \$1,000,000.

Hotel Madison, Wis., to S. M. Siesel Co., Milwaukee, \$1,000,000.

Bids Wanted on Big Jobs

Among the projects on which bids are either asked or will soon be called for, in Construction News, pp. 1 to 10, are the following:

Railway, 22 mi., Orchard to Perkins, Idaho, for Oregon Short Line R.R., \$3,000,000.

Hospital, Kansas City, Mo., for Heart of America Hospital, \$2,000,000.

Hospital, Louisville, Ky., for St. Joseph's Infirmary, \$1,500,000.

Gas pipe line, from Ranger-Eastland to Judd, Texas, for Lone Star Gas Co., \$1,350,000.

Hotel Milwaukee, Wis., for Hotel Wisconsin, \$1,000,000.

Wharf and terminal, Corpus Christi Tex., for Neuces Co., \$1,000,000.

Temple, Milwaukee, Wis., for Elks Bldg. Comm., \$1,000,000.

Average Weekly Value of June Contracts Let Over Thirty Per Cent Heavier Than in 1922

Total of 2,763 Awards During June, Average Value \$68,326
Compared With 1,016 in May, Averaging \$215,267

Contracts awarded in the four issues of *Engineering News-Record* during June, totaled \$188,786,000 as compared with \$218,712,000 in the five issues of May. This represents an average weekly value of \$47,196,500 for June, against \$43,742,000 during the preceding months.

The weekly average of \$47,196,500 for the months of June represents an increase in money value of over 30 per cent above the weekly average for the

corresponding period in 1922.

The number of awards totaled 2,763 during June, with an average value of \$68,326 as compared with 1,016 in May averaging \$215,267 per contract.

Minimum costs observed in Construction News on each class of constructions are as follows: Water-works, \$15,000; other public works, \$25,000; industrial construction, \$40,000; and commercial buildings, \$150,000.

Of the \$188,786,000, a total of \$10,-

199,000 represented Canadian awards, which fell off heavily from the May totals.

The gain during June may be attributed principally to large private building construction. A general falling off in public building construction has been evident during the last month. The marked gains in private projects are exemplified by such instances as the New York Telephone Exchange building, thirty stories, \$11,250,000; a twenty-four story office building also in New York, \$5,000,000; a twenty-one story bank and office in Chicago, \$5,500,000, and a twenty story office also in Chicago, \$7,000,000. Other projects include a packing plant, a cement mill, schools, commercial buildings and hotels.

Engineering News-Record Construction Cost Index Number

July, 1923	222.10
June, 1923	220.70
July, 1922	169.70
Peak, June, 1920	273.80
1913	100.00

Engineering News-Record's Construction Cost Index Number advanced 1.4 points since last month due to stiffening in labor rates. Prices of basic materials remained unchanged during month except for slight drop in lumber. The average rate for common labor is now 54c. Thus, general construction cost is 31 per cent higher than one year ago and 19 per cent under the peak; it is 122 per cent above the 1913 level.

Engineering News-Record Construction Volume Index Number

Monthly	
June, 1923 (4 issues of E. N.-R.)	148
May, 1923 (5 issues of E. N.-R.)	171
June, 1922 (5 issues of E. N.-R.)	187
1913	100
Yearly	
1922 (entire year)	130
1921 (entire year)	88
1920 (entire year)	91
1913	100

Engineering News-Record's Construction Volume Index Number is 148 for the month of June, and 130 for the whole of 1922, as against 100 for 1913. This means that the actual volume of construction in 1922 (not the mere money-value of the contracts let that year) is 30 per cent above the volume of construction for 1913. Our monthly volume number, 148 for June, 1923, is really the increment of construction, and indicates the rate at which contracts are being let as compared with 1913 awards.

VALUE OF CONTRACTS LET IN THE UNITED STATES AND CANADA DURING JUNE, 1923

	New England	Middle Atlantic	Southern	Middle West	West of Mississippi	Western	Total United States	Canada	Total
Waterworks		\$198,000	\$253,000	\$2,031,000	\$1,160,000	\$186,000	\$3,826,000	\$217,000	\$4,043,000
Sewers	\$295,000	2,360,000	567,000	2,459,000	493,000	249,000	6,423,000	78,000	6,501,000
Bridges	28,000	154,000	178,000	518,000	913,000	241,000	2,032,000	258,000	2,290,000
Excavation, drainage and irrigation		173,000	25,000	174,000	745,000		1,117,000	57,000	1,174,000

Labor Rates and Conditions Throughout the Country

Three factors dominate the construction situation: (1) scarcity of certain basic materials and labor, which causes (2) very high cost, which is causing (3) curtailment of building. With these three factors, three others of a more general nature must be considered: (1) heavy freight traffic caused by (2) heavy production of materials to fill orders already placed. The third general factor is the uncertainty of the stock market.

As proving that present conditions remain favorable to labor, the common-labor rate for the nation, as applied to pick-and-shovel men is placed at 54c.

per hour as against 53c. last month, according to *Engineering News-Record* figures. Local building conditions are as follows:

Atlanta—Building continues active with plenty of materials.

Baltimore—Scarcity of skilled building trades mechanics.

Birmingham—Scarcity of hodcarriers and common laborers, due to migration of negro labor to the North.

Boston—Plenty of building trades mechanics except common laborers and bricklayers, latter threaten strike. Construction falling off.

Dallas—Excessive demand for brick-

layers; fair demand for carpenters; slight unemployment in common labor. No falling off in building construction.

Denver—Building trades 100 per cent employed.

Detroit—More men available for construction work because of slight unemployment at industrial plants. Demand for men on some jobs causing a "bidding up" of wages in special cases.

Kansas City—Shortage of bricklayers; plenty of other crafts. Structural iron workers granted rise.

Minneapolis—Postponement of many large building projects because of high materials prices.

Montreal—Scarcity of bricklayers; other crafts plentiful. Hodcarriers and common laborers granted wage advance.

New Orleans—Bricklayers demand wage advance of 25 per cent above present scale, effective July 7. Carpenters granted advance of 5c. per hour without signed agreement. This craft voluntarily reduced its own wage scale during the recent depression, when the matter of wage reductions was being agitated. Negotiations pending with other trades.

New York—Bricklayers awarded con-

tract of \$12 per day for two years, an advance of \$2 per day above the 1920 basic wage scale, thereby ending the strike begun on May 21. Hodcarriers will also receive \$8 against \$7 per day during the same period. Inside ironworkers are on strike for forty-four hour week and abolition of the open shop. Cement and concrete workers are also on strike, demanding \$7.50 per day, an increase of 30c. over the rate offered by the employers.

Pittsburgh—Scarcity of hoisting engineers; other crafts plentiful. Very

slight slowing down in steel mill operations due to hot weather.

St. Louis—Bonuses of \$1 to \$3 per day offered bricklayers. Basic wage \$1.50 per hr., same as New York. Plasterers who went on strike two weeks ago granted advance from \$12 per day to \$14. Helpers also granted rise of \$1 per day, making present rate \$10.

San Francisco—Plenty of work for all trades. Threatened strike of carpenters held up, settlement not yet effected.

Monthly Prices of Construction Materials

Ups and Downs of the Market

Pig Iron—Recent declines due mostly to increased production and unusually large old-material supply. Present market, however, trifle steadier. Birmingham base on No. 2 foundry, still \$27 per gross ton.

Railway Supplies—Car materials still hold lead in demand at mills. Track supplies higher at Birmingham. Spikes and bolts declined in St. Louis; track bolts somewhat lower at Pittsburgh mill. No change in rails and ties.

Pipe—Birmingham mill base on 6-in. cast-iron pipe remains at \$49 per ton. San Francisco warehouses; however, advanced 4-in. and 6-in., \$2 per ton. Stiff advances in wrought steel pipe and clay drain tile in St. Louis. Sewer pipe higher in Birmingham, St. Louis and Atlanta, due to increased labor costs.

Road and Paving Materials—Road-oils and asphalt prices firm during month. Expected cut in crude-oil prices due to heavy production and reserve stocks. Granite paving blocks advanced \$5 per M. in Boston and 5c. per sq. yd. in St. Louis. Wood blocks higher in Minneapolis and Boston; lower in St. Louis.

Sand, Gravel and Crushed Stone—Gravel, 1 ½-in., up 15c. in Kansas City;

¾-in. down 25c. per cu. yd. in Minneapolis. Sand declined 20c. in Cincinnati and 15c. per ton in Birmingham, during month. Crushed stone declined, somewhat, in Cincinnati, St. Louis and Boston.

Lime—Hydrated finishing, advanced 50c. in Boston and declined 50c. per ton in Dallas. Hydrated common rose 50c. in Boston and 90c. per ton in Cincinnati. Common lump lime dropped 15c. per bbl. in Dallas and \$1 per ton in Montreal, during month.

Cement—Prices firm throughout the country. Birmingham quotes advance of 20c. per bbl., due mainly to higher labor costs. Twenty-eight other cities report no change.

Structural Steel—General price level remains unchanged. Bars still quoted at \$2.40 per 100 lb., with plates and shapes at \$2.50, on new contracts. Price tendency on structurals has been slightly lower recently; inquiries, however, have improved during the last week. Mill operations at about 89 per cent of capacity, against 94 per cent two months ago. Considerable improvement in new plate business, mostly in small lots.

Brick and Hollow Tile—Common

brick advanced 20c. in Dallas, 50c. in Detroit and from 50c. to \$2.50 per M. in Birmingham, due to increased demand and higher labor costs. Cincinnati, however, reports slight drop in brick. Hollow tile advanced in Cincinnati, Boston and St. Louis. Declines reported in Chicago, Cleveland and Minneapolis; in last mentioned city, drop due to lower delivery charges.

Lumber—Price tendency downward throughout the country, due to falling off in demand. Postponement of building projects responsible for lessened demand. Slight increases in pine, however, reported in Boston and Dallas, with fir tending upward in Cincinnati.

Explosives—Declines reported in New York, St. Louis, Denver, Atlanta and New Orleans on 40 and 60 per cent gelatin dynamite. Dallas, however, quotes slight advance during month.

Scrap—Prices to dealers and producers down \$2 per gross ton f. o. b. New York, during month.

Lined Oil—Raw oil (5 bbl. lots) quoted at \$1.13 f. o. b. New York, against \$1.16 per gal, one month ago. Chicago quotes \$1.28, compared with \$1.37, as of June 7. Downward tendency reported in Dallas and Atlanta.

Price advances since last month are indicated by heavy type; declines by *italics*

PIG IRON—Per Gross Ton—Quotations compiled by The Matthew Addy Co.:

Birmingham—Quotes carload lots, f.o.b. sidings; \$4.00 additional per M. ft. to contractors.

Boston and Cincinnati—Prices to contractors in carload lots, f.o.b.

Denver—Quotes dealers price to contractors on large projects.

St. Louis—Wholesale price to contractors, f.o.b. cars, \$3 per M. ft. additional.

Seattle—Price to contractors, delivered.

Dallas—Wholesale to contractors, \$10 per M. ft. additional.

FREIGHT RATES

On finished steel products in the Pittsburgh district, including plates, structural shapes, merchant steel, bars, pipe fittings, plain and galvanized wire nails, rivets, spikes, bolts, flat sheets (except planished), chains, etc., the following freight rates are effective in cents per 100 lb., in carloads of 36,000 lb.:

Baltimore	\$0.31	Detroit	\$0.29
Birmingham	.69	Kansas City	.735
Boston	.365	New Orleans	.515
Buffalo	.265	New York	.34
Chicago	.34	Pacific Coast (all rail)	1.34
Cincinnati	.29	Philadelphia	.32
Cleveland	.215	St. Louis	.43
Denver	1.27*	St. Paul	.60

*Minimum carload, 40,000 lb.

*Minimum carload, 50,000 lb., structural steel only; 80,000 lb., for other iron and steel products.

MISCELLANEOUS

STEEL SHEETPIILING—The following price is base per 100 lb. l. n. b. Pittsburgh, with a comparison of a month and a year ago:

July 5	One Month Ago	One Year Ago
\$2.65	\$2.65 @ 2.75	\$2 00

WIRE ROPE—Discounts from list price on regular grades of bright and galvanized are as follows:

	Eastern Territory
Hercules red strand, all constructions	20%
Patent flattened strand, special steel wire rope	20%
Patent flattened strand, iron rope	5%
Flow steel round strand rope	35%
Special steel round strand rope	30%
Cast steel round strand rope	20%
Round strand iron and iron tiffen	5%
Galvanized steel rigging and guy rope	71%
Galvanized iron rigging and guy rope	+121%

California, Oregon, Nevada and Washington Discount 5 points less than discount for Eastern territory.

Wyoming, New Mexico and Colorado: Discount 5p. into less than discount for Eastern territory.

Arizona: Discount 10 points less than discount for Eastern territory.

Montana, Idaho and Utah: Discount 10 points less than discount for Eastern territory.

North Dakota, Nebraska, Kansas, Oklahoma and Texas: Discount 5 points less than discount for Eastern territory.

MANILA ROPE—For rope smaller than 1-in. the price is 1 to 2c. extra; while for quantities amounting to less than 600 lb. there is an extra charge of 1c. The number of feet per pound for the various sizes is as follows: 1-in., 8 ft.; 1-in., 6 ft.; 1-in., 4 ft.; 1-in., 3 ft.; 1-in., 2 ft. 10 in.; 1-in., 2 ft. 4 in. Following is price per pound for 1-in. and larger, in 1200-ft. coils:

	\$0 18	New Orleans	\$0 18
Boston	18	Los Angeles	18
New York	18	Seattle	18
Chicago	18	St. Louis	19
Minneapolis	18	Montreal	19
San Francisco	20	Detroit	19
Atlanta	22	Baltimore	20
Denver	21	Kansas City	20
Cincinnati	15	Birmingham	20
Dallas	15	Philadelphia	20

EXPLOSIVES—Price per pound of dynamite in small lots:

	40%	Gelatin	60%
New York	\$0 27	\$0 295	
Boston	23	25	
Kansas City	225	25	
Seattle	225	25	
Chicago	22	25	
Minneapolis	1967	2173	
St. Louis	22	245	
Denver	2025	2875	
Dallas	20	25	
Los Angeles	17	20	
Atlanta	23	2575	
Baltimore	23	23	
Cincinnati	25	25	
Montreal	195	235	
Birmingham, delivered	16	17	
New Orleans	195	220	
San Francisco	1625	1925	
Philadelphia			

PILES—Prices per lineal foot, pine piles with bark on, f.o.b. New York.

Diameters	Points	Length	Barge	Rail
12 in. at butt.	6 in.	30 to 50 ft.	\$0 14	\$0 18
12 in.—2 ft. from butt.	6 in.	50 to 59 ft.	19	23
12 in.—2 ft. from butt.	6 in.	60 to 69 ft.	21	25
14 in.—2 ft. from butt.	6 in.	50 to 69 ft.	25	34
14 in.—2 ft. from butt.	6 in.	70 to 79 ft.	27	36
14 in.—2 ft. from butt.	5 in.	80 to 89 ft.	35	41

SCRAP—The prices following are per gross ton paid to dealers and producers f.o.b. New York. In Chicago and St. Louis the quotations are per net ton and cover delivery at the buyer's works, including freight transfer charges.

	New York	Chicago	St. Louis
No. 1 railroad wrought	\$15 00	\$11 50	\$16 00
Stove plate	12 00	12 00	15 00
No. 1 machinery cast	18 00	16 50	20 00
Machine shop turnings	11 00	4 50	12 00
Cast borings	12 00	12 00	12 00
Railroad malleable cast	13 00	12 50	20 00
Re-rolling rails	13 00	13 00	19 00
Relaying rails		30 00	28 50 @ 36 50
Heavy melting steel	12 00		

SHIP SPIKES—Current prices per 100 lb.:

	San Francisco	Seattle
In.	Galv.	Black
1	\$9 85	\$7 65
2	7 80	6 30
3	7 75	6 15

Pittsburgh base in lots of 200 kegs or more, \$3.50 @ 3.75.

ENGINEERING NEWS-RECORD

DEVOTED TO CIVIL ENGINEERING
AND CONTRACTING

D. J. MEHREN, Editor

Volume 91

NEW YORK, JULY 12, 1923

Number 2

Public Opinion Wins

JUDGE GARY and his associates in the steel business have had their ears to the ground since their inept report of last month in which they questioned the early possibility of abolishing the 12-hr. day. The head of the Steel Corporation now finds that he is "decidedly opposed to the 12-hr. day" and that, "practically all the manufacturers of iron and steel in this country have positively agreed to the entire abolition of the 12-hr. day as soon as there is sufficient labor to permit it." This is a return to that appreciation of public sentiment that has generally characterized the Steel Corporation. Unquestionably, there are tremendous labor difficulties involved in the turn to the shorter shift, but they are far from insurmountable. In view of the interest the public is taking in this issue there is every reason to believe that the President will see that effort is made to bring about the reform at the earliest possible date.

Who Restricts Apprentices?

RESTRICTION of apprentices has been a common complaint against labor unions. The condemnation is a general one. We are told that one of the reasons for the shortage of building mechanics is that the unions restrict entrance into the trades. Whatever may be the truth in specific instances and places the facts at New York at least do not warrant the charge. There it is the contractors and not the unions who restrict apprentices. For example, in the carpenter trade union rules would permit of the employment on New York operations of 2,600 apprentices. As a matter of fact, there are only 800 in the city. The painters' and decorators' unions would allow 800, but only 125 apprentices are to be found. In general, there are at work only 40 to 50 per cent of the apprentices allowed by union rules. The only exceptions are in the brick-laying and the electrical trades where the quotas are nearly full. Where the number of apprentices is below quota the reason invariably is that the contractors are unwilling to go to the trouble of training the boys. Of course, union rules do place limitations on apprentices, but until the time comes when the contractors have employed all the apprentices that the unions allow, contractors have no reason to complain against union restrictions and the public's charge against the building industry should lie at the door of the contractors and not at that of the unions.

Building Height Uncertainties

LIMITATION of city building heights by law seems to be in an epidemic stage at the moment. Half a dozen cities have concerned themselves with the question in recent months. Their conditions are quite different, and the apparent motives of the height limitation movement are just as various. In one or two cities the protection of a particular building or street

appears to be at issue, while in others the objective is more general. In still other cases no immediate motive is apparent. Except in one case, it is proposed to restrict the height of future building to a lower point than the owner's or architect's choice would fix. The exception is Boston, where existing height limits on a particular street are to be raised in order to permit better utilization of the land. Nowhere, however, has substantial reasoning been brought to bear on the problem. So far as can be judged, esthetic notions are leading factors in the discussion—a belief that high buildings are unsightly in themselves or are harmful to neighbors, or the vague notion that civic beauty lies in a uniform sky line. Such beliefs do not appeal very strongly to the general run of men, and the successful development of tall buildings in both isolated and row arrangements, and the strong demand for space in them, are practical answers to many of the claims made by those who advocate restriction. Transportation difficulties, or other real objections arising out of the intense concentration of population which high buildings produce, have almost never been made an argument in height limitation, nor have they been studied with due care to determine their bearing on the problem. In cities of large size and great concentration of business these difficulties and objections are serious—though just how serious is somewhat uncertain—while in smaller cities they are substantially non-existent. In the meantime the esthetic discussion of high buildings remains largely a matter of diverging personal views, and the skyscraper has rapidly become a feature of even the smaller country metropolises, where for many decades to come such matters as zoning and setbacks can have no meaning. Until a full and convincing study of the relation of the skyscraper to community life and to the rights of different parties has been made, it is not likely that the height restriction movement will progress beyond the condition of breaking out in an occasional epidemic, as at present.

For a New Niagara Treaty

EVENTS are shaping themselves for an early revision of the treaty provisions for the use of the water power on the Niagara and St. Lawrence Rivers. On this side of the boundary the new tunnel and power house of the Niagara Falls Power Co. is nearing completion, while in Ontario the Queenston power house has nearly its full installation in wheels. This means that there are available power units in capacity far in excess of the flowage permitted under the existing treaty and water is running to waste over the Falls, water that is in no way necessary to the scenic grandeur of that spectacle. Moreover, the recent election in Ontario brings back into power the supporters of government owned and operated power, notably Sir Adam Beck, the father of the Ontario "Hydro." This new administration is committed to the utmost development of all the border water flowing by the province. Both

political and industrial demands make imperative that some international agreement be reached whereby Canada gets more than the 36,000 sec.ft. and the United States more than the 20,000 sec.ft. now permitted. The two governments are in possession of all the necessary hydraulic data and the discussion now is in the realms of diplomacy, with the customary jockeying inherent in diplomatic discussion, but it can hardly be doubted that the pressure from both sides of the boundary for some settlement will soon bring about at least a temporary agreement from which later a new treaty will evolve.

The Penalty of Neglect

THE present water shortage in portions of northeastern New Jersey affords an example of the penalty of neglect. There is most cause of alarm in the Elizabeth-Plainfield section where it has been known for years that twenty communities served by five water companies might face a serious water shortage any day. The communities and the companies have agitated the question from time to time but with no fruitful result. The State Conservation and Development Commission obtained from Allen Hazen a comprehensive report showing that water in plenty for decades to come could be had for northeastern New Jersey by carrying out any one of several water storage possibilities (see *Engineering News-Record*, March 16, 1922, p. 430). A commission to provide a joint supply for wholesale distribution and for co-ordinating the various municipal and private water purveyors in northeastern New Jersey was proposed by Mr. Hazen. The municipalities, the water companies, and the public at large in northeastern New Jersey seem to have been indifferent to the Hazen report. The major difficulty in this New Jersey region lies in the fact that while various private water companies are trying, naturally enough, to conserve their own interests in the most readily available sources of supply, and have largely consolidated their interests, the municipalities have never worked in unison to meet their water needs. If the cities and towns could unite under able leadership, as was suggested in the Hazen report, the water companies would doubtless fall quickly into line and all northeastern New Jersey might soon be insured of a plentiful, reasonably cheap and pure water supply for a century to come.

Service Charge Unpopular

ALTHOUGH based on sound reasoning designed to distribute equitably the cost of water, gas and electric current, the service charge is unpopular. This is reflected by statute or utility commission prohibitions in some states. A statute enacted this year by the New York legislature is directed against gas companies. After providing that "every gas corporation shall charge for gas supplied a fair and reasonable price" it prohibits "an additional charge or fee for service or for the installation of apparatus or the use of apparatus installed." Neither the public or the lawmakers realize that if service charges are prohibited then the rates for gas or water or electric current must be raised and that it is difficult if not impossible to do this without overburdening some consumers and favoring others. Consumers regard the service charge as a device of the corporation to raise profits already extortionate. Unfortunately the service charge in the past has been and in some quarters even now is used as a means to this end; but not where there is sound

public utility regulation. A vast amount of educational work, combined with impartial utility commission administration and whole-hearted co-operation by the utility corporations, will be required in some states before the public will cease to chafe under the service charge. Meanwhile, if legislatures or commissions forbid the service charge then its equivalent must enter into the unit consumption rates—a plan that for a long time to come will probably cause less friction than the other—if for no other reason than because it is not recognized by the consumer.

Concrete for Study

THE discussion on the behavior of concrete by the American Society for Testing Materials was distinctly worth while. Only a few hundred engineers were present and but a few of them took part but the printed record will be extensive and inclusive enough to carry emphasis where emphasis was sought. If the discussion serves to focus attention upon the characteristics of concrete as exhibited in service and not in tests, its purpose will have been achieved.

There was some misapprehension as to the effect of such a symposium and a disposition to regard it as an attack on concrete. Such could hardly be the case. With upwards of 125,000,000 bbl. of cement going into concrete this year there can be no question as to its secure position as an engineering tool. That very security is its own protection against unwarranted attack. Without portland cement and the concrete which it makes possible the civil engineer today would be thrust back a quarter-century in the solution of most of his problems. But because concrete has had a wonderful development is no reason to consider it a perfected product or even to consider that all of its specific failures to achieve perfection are due to misapplication of known methods. We are far from knowing all there is to know. The true scientific spirit of trying to learn more was behind the symposium and all concrete users will be benefited in the degree which they, too, can become possessed of that spirit.

This inquiry toward perfection, however, has two phases. One was represented by the group of men who took part in the symposium, men who are well acquainted with the extended investigations into the nature of concrete and its behavior in tests and, to some degree, in service and who therefore are disposed to consider that most deficiencies in concrete are due to the non-observance of established rules, but who at the same time recognize the gaps in present knowledge. The other, and more serious, phase is represented by the larger body of concrete users who, if the truth be told, are blandly ignorant of any but the elementary information of what concrete really is and how it should be made but who are in the end really responsible for a large part of the concrete that is placed. In this latter class are most of the concrete foremen, practically all concrete workmen and too many engineers and contractors who pride themselves on having placed thousands of yards of concrete and on their expert knowledge of its technique.

A reading of the discussion will show that the experts, with a few exceptions, lay most emphasis on an insistence on the rules of making concrete. It is acknowledged that there are examples of poor concrete which cannot be classed under any of the known

diagnoses; sea water and alkali exposure are particularly elusive. It is admitted that the optimum amount of water, not especially well defined at best, can rarely be used in real construction. There are certain peculiarities of aggregate which lead to trouble but which so far we have not been altogether successful in discovering or predicting. Density, or perhaps better impermeability of surface, the great desideratum, is easier to demand than to get. Study to supply these deficiencies is recommended but the major insistence is on observance of rules.

The one exception to that group is a smaller body of students of concrete who feel that there is great opportunity for a development in cement which will lead to a better concrete. This group was ably represented at the symposium by P. H. Bates, of the Bureau of Standards. Mr. Bates' discussion is a challenge to those who know enough about the nature of cement and the methods of its manufacture to discuss intelligently any proposals for its improvement. It must be admitted that few engineers come in that category, but engineers can appreciate the fundamental requirements for concrete laid down by Mr. Bates and the deficiencies of cement in meeting them. How to improve portland cement to make up these deficiencies or to devise a new cement which will be acceptable must be left to those in the cement industry and to the few scientists and specialists outside that industry capable of studying the problem.

It is clear, however, that the one standard for cement while a most necessary stabilizing influence in the development stage of that material need not be considered the ultimate aim. So long as concretes made from different cements all passing the standard specification react differently to the same conditions it cannot be said that we have a satisfactory specification. The only ultimate solution is either to devise a specification which does indicate similar prospective reactions or to formulate different specifications for differing material.

It is true, as Mr. Kinney pointed out, that the conditions of cement manufacture with its scattered plants so located as to serve certain territories with a minimum of haulage make a uniform product economically desirable; it is also true that a multiplication of standards would be confusing both to producer and consumer. But it is conceivable that one standard would cover the major part of concrete used and that the special types would be applicable to the concrete subject to the kind of exposure that has given the greatest trouble, such as for floors, extreme weather exposure, sea water and alkali. If cements better suited to these uses can be devised the additional cost due to special manufacture would doubtless be absorbed by the user. Meanwhile it is reassuring to hear from a representative of the cement manufacturers that that industry realizes the seriousness of this demand and is engaged in a study of the nature of cement and its methods of manufacture of greater scope and more serious intent than ever before attempted.

The other phase of this inquiry into concrete behavior is something which all concrete users may take to heart. In spite of the vast amount of publicity work that has been done there are many immediately responsible for the mixing and placing of concrete, and even of the selection of the materials which make it up, who pay no attention to what are acknowledged to

be elementary rules for making concrete. This is due sometimes to ignorance but more often to poorly placed self confidence. The foreman who never saw a piece of concrete he supervised five years after he placed it goes serenely ahead putting in what he has established in his mind as "good concrete" without ever knowing whether similar "good concrete" placed in the past has stood up or is going to pieces. The disease extends sometimes higher up than the foreman. Its cure lies in publicity; in constant hammering by those who do know what can happen to bad concrete; in more attention to the actual mixing and placing of the concrete; in better supervision and better inspection.

The education of the ignorant and self-complacent and the study of the yet unsolved problems of cement and concrete will be both furthered by such discussions as took place at Atlantic City. Concrete is too valuable an asset to the constructor for him to be satisfied with its present development.

Warning the Coal Men

FAIR warning to both miner and operator is the keynote of the anthracite report of the President's Coal Commission. The public must be protected against exorbitant prices and the distress of shortage incident to strikes. The commission is evidently fair and tolerant, but it is clearly convinced of the public interest inherent in the coal business—the Supreme Court's opinion in the Kansas Labor Court case to the contrary notwithstanding—and its recommendations all look toward a protection of that interest. As was foreshadowed in the earlier report government regulation, not government ownership, is recommended. But that regulation is not to be mandatory unless the two contracting parties in coal production are unable to come to an agreement which protects the public in both price and delivery.

In such an emergency government control is recommended. At other times the governmental interference would be confined to an investigation of the degree to which the public is in need of protection, with power to act to remedy any "conspiracy of either operators or miners, or both, directed against the general welfare of the people."

There is no specific charge that anthracite coal costs the public too much, but there is intimation that reduction in freight rates, royalties and dealer profits can be brought about. The commission evidently hopes that the presentation of the facts—not all yet available—will be impressive enough to bring both operator and miner to a better appreciation of the public's point of view, under the increasing threat of ultimate government control.

The representative and yet diverse character of the commission inspires respect in its report. Everyone in the coal industry must accept that; they will do well to go about the readjustment of their business in line with the commission's recommendations with the realization that the public is in a mood to get coal when they need it and at a fair price. The commission gives the industry a chance to do this without much interference from the government. If the industry fails—and the commission wants legislation to make sure that the government will know when it does fail—there is little doubt that the public will step in to run the coal industry itself.

spanning this section, extend 5 ft. below the tops of the walls. The river bed is sand and gravel. Originally the river followed a winding course through its flood plain in Pueblo, but as the city grew it was slightly straightened. This straightened channel has a capacity of only 37,000 sec.-ft., while the maximum discharge of the flood of 1921 is estimated at 90,000 sec.-ft.

The 1921 Flood—The flood of June 3-5, 1921, was caused primarily by localized cloudbursts during the afternoon and night of June 3 over the mesas and in the foothills between Pueblo and Canon City, and was due to the runoff of less than 10 per cent of the drainage area above Pueblo. In the Boggs Flats district, about 15 miles southwest of Pueblo, more than 12 in. fell in 7 hr. or less; at Colorado Springs, about 45 miles north, 9.40 in. fell in 10½ hr.; and at Penrose, about 25 miles northwest, 7 in. fell in 17 hr., while the rainfall in Pueblo amounted to only 2.88 in. during 12 hr. In the Dry Creek drainage area, just northwest of Pueblo, a cloudburst possibly more intense than that of the evening of June 3 fell on June 2, but it did no appreciable damage at Pueblo. The rain continued at intervals in various parts of the valley during June 4-8, causing the failure on June 9 of the Schaeffer Dam, on Beaver Creek, about 30 miles northwest of Pueblo.

The main flood in the Arkansas River at Pueblo occurred during the night of June 3-4, the water beginning to rise at about 5 p.m. and reaching the crest of 24.7 ft. at the Main St. gage at midnight—a total rise of 20 ft. in 7 hr. Before 1 a.m. the river began to fall, and by 5 a.m. was down to about the tops of the levees. Fountain Creek, with a fall of 25 ft. per mile, had not reached appreciable flood proportions at 1 a.m., but developed a violent flood a few hours later, reaching a crest flow of 50,000 sec.-ft. at 4 a.m.

The flood runoff was confined to the territory below Canon City. No damage occurred at Canon City and practically none at Florence, 27 miles above Pueblo. Below Florence, the damage increased rapidly and was greatest at Pueblo, where the property damage is estimated at over \$10,000,000. Hundreds of dwellings were swept away and many buildings were wrecked. The loss of life in the city was great; the official list of 78 bodies recovered doubtless fails to include all the deaths. Of the nine railroad bridges in the city, eight were either seriously damaged or completely destroyed; portions of the yards were badly wrecked or buried in sediment, and much equipment was washed away or seriously damaged. The intangible losses were very great.

Flood Possibilities—Indian legend tells of a flood much greater than that of 1921 which occurred prior to the settlement of the Arkansas Valley, probably in 1844. Newspaper articles together with statements of early settlers indicate that floods of considerable magnitude occurred in 1855, June 1864, May 1867, June 1869, August 1889, July 1893 and May 1894. The flood of June 11, 1864, seems to have been comparable in size with the flood of June 3, 1921. The flood of May 30, 1894, was the most destructive in the history of the valley prior to 1921; its maximum height was about 6 ft. lower than the flood of 1921, and surveys made by the city engineer at the time indicated that the maximum discharge was about 40,000 sec.-ft. Next in size was the flood of July 26, 1893, which reached a height about 10 ft. lower than that of 1921.

It is impossible to work out any very satisfactory

flood-frequency relation from the brief records available for the Arkansas River. About all that can be said is that there have been three floods of 40,000 sec.-ft. or more at Pueblo in 75 years, or one in about 25 years, and that two of these may have exceeded 90,000 sec.-ft.

Far less is known about floods in Colorado than might be desired, and the determination of what constitutes a reasonable degree of protection is in the main a matter of judgment supplemented by studies and experience elsewhere. American storm rainfall records, studies of cloudburst rainfalls and of great floods in this country and in Europe, theoretical studies of the total amount of water which can be retained in the atmosphere and concentrated in any one locality under given conditions, and probabilities of various possible condi-

FIG. 2—PART OF DRAINAGE AREA ABOVE PUEBLO

tions and combinations of rainfall occurrence were considered in this connection. Thus, if the Boggs Creek cloudburst, which caused a discharge of over 55,000 sec.-ft. in the St. Charles River at 1 a.m. on June 4, had centered five miles farther north, this additional runoff would have been transferred into the Arkansas River and might have nearly doubled the peak discharge through Pueblo.

The conclusion reached was that the protection works should be made adequate to care for a flood two or three times as great as that of 1921, depending upon the relative duration and intensity of the rainfall causing the flood. Other requirements for a satisfactory plan were that the cost must be well within the resulting benefits; the construction should be as beneficial and of as little detriment to the city as possible; it should cause a minimum of disorganization and rearrangement; and it must be adapted to future requirements of a growing city. The railroad tracks and yards adjacent to the river were an important factor in determining the plan. The chief engineers of the various railroads held a number of meetings at Pueblo in an effort to assist in working out the problem, and further co-operated by making available maps, plans and data. All possible plans or methods of control were studied.

Adopted Plan—Fig. 1 shows the central part of Pueblo, as it is now and as the flood-control plan just adopted will change it. The business section centers roughly at the intersection of Union Ave. and Main St.

and extends southwesterly to the bluffs just beyond the Denver & Rio Grande Western Ry. yards. Fountain Creek, to the east, is separated from the business district by a prominent ridge, and joins the Arkansas River well below the city. The plan provides for moving the present Arkansas River channel in Pueblo to a new location along the bluffs at the south edge of the valley floor. It also provides a small retarding basin formed by the construction of a barrier at Rock Canyon, 6 miles above the city, for the purpose of regulating the flow of great floods before they reach Pueblo; the effect of this barrier is to cut off the peaks of extreme floods.

A disadvantage of the plan is that its first cost would be about half a million dollars more than the plan for a large retarding dam at Rock Canyon. Another possible disadvantage is that it disturbs the Denver & Rio Grande Western Ry. freight yards. Its advantages are

depending upon the relative duration and intensity of the rainfall causing the flood.

The channel along the foot of the bluffs at the south side of the valley will extend from the mouth of Dry Creek, which enters the Arkansas River just above Pueblo, to Santa Fe Ave., where the Santa Fe Trail enters the city from the south, and will be constructed partly by excavation and partly by a levee along the left or north bank, the bluff serving as the other bank. The grade will be 10 per cent steeper than the average present grade, tending to a self-maintaining channel. From its lower end a small channel will be excavated through waste lands from Santa Fe Ave. to the present river channel at the Colorado & Southern Ry. bridge, for carrying the low-water flow eastward from the mouth of the deep channel.

Channel—The location, requiring a high paved levee

FIG. 3.—ROCK CANYON RETARDING DAM

numerous. The physical conditions inherent to the new channel location are favorable both as to cost and as to the degree of protection. The protection it affords is, with one exception, equal to that of any other feasible plan; it gives positive protection against floods from Dry Creek; it improves the streets at their crossings of the present channel; it opens Santa Fe Ave., the main thoroughfare from the south, avoiding undesirable grade crossings at the present channel; it decreases the number of bridges to be maintained by the city, county and railroads; it benefits the railroads operating in Pueblo; it greatly improves the appearance and attractiveness of the city, and makes important improvements in the general arrangements that are conducive to future development and growth; and it improves the channel alignment.

Space is available for a wide channel between important railroad structures and the bluff. There are limits to the desirable width and depth and flow velocities, which have been recognized in the design; the further control which is necessary is accomplished by the retarding barrier above Pueblo. The greatest flow through Pueblo will be limited to 125,000 sec.-ft., made up of a maximum outflow of 100,000 sec.-ft. past the barrier, and a coincident flood peak of 25,000 sec.-ft. from Dry Creek. The plan will protect Pueblo from a flood two or three times as great as that of 1921,

on only one side, and involving a levee height which does not obstruct travel, has made it possible to design the channel for deep flow. The bottom grade is a continuation of the river bottom above and below the city. With maximum flow there will be a paved freeboard of 2 ft. The present value of the waste land below Santa Fe Ave. is not sufficient to warrant the cost of protecting it. A channel only large enough for low-water flow will be constructed here, with the expectation that water will overflow during times of flood. At any time in the future the protection could be continued below Santa Fe Ave.

The main levee, forming the left or north bank of the new channel, begins at the easterly end of the proposed railroad bridge over Dry Creek and runs to Santa Fe Ave. A similar levee will form the right bank of the new channel at its lower end after it turns away from the bluff. These levees will have a top width of 8 ft., a land-side slope of 2 to 1, and a water-side slope of $1\frac{1}{2}$ to 1; the latter will be paved with concrete to 2 ft. above the high-water line.

The levees extending up Dry Creek are too high to be crossed by the tracks west of the Denver & Rio Grande Western freight yards without causing undesirable grades within the yard. The tracks are therefore carried across the stream at a level 8 ft. below the levee tops on a heavy watertight concrete bridge having

sides built up to the levee grade and at the ends connected to the levees.

Railroad Changes—The plans for railroad work aim to give the railroads every advantage of rearrangement possible at a cost to the district not to exceed the damage to the railroads by reason of the property taken. Yards and tracks of the Denver & Rio Grande Western Ry. which must be moved from their present location along the foot of the bluff are replaced by a new yard north of the new channel, extending from the westerly end of the Union Depot tracks to Dry Creek. The north unit, or that comprising all but the southerly seven tracks of the new yard, together with connecting tracks and new ice-house tracks, are to be completed ready for operation before any existing tracks are disturbed. This change will also include the construction of a new 15,000-ton ice house, freight house, coaling plant and several new roundhouse stalls. The Union Depot tracks are slightly altered but the building is not disturbed. Five single-track railroad bridges across the present river channel become unnecessary under the changes effected by the plan.

Abandonment of the present river channel makes possible the replacement of the former Santa Fe Ave. highway bridge and grade crossings by a modern subway under the four railroad tracks. Four highway or street bridges are provided across the new channel, and one double-track railroad bridge.

Retarding Basin—At the site of the retarding barrier, the river runs through a gorge 60 ft. wide and 20 ft. deep in solid Dakota sandstone formation. The barrier will consist of a concrete spillway 500 ft. long between two concrete wingwall abutments, containing an open notch outlet at the gorge, and earth fill extending from the abutments to high ground at the sides of the valley. The outlet notch will be proportioned to discharge about 84,000 sec.-ft. under assumed extreme flood conditions. In addition, two conduits for the Denver & Rio Grande Western double-track railroad and one for the Bessemer irrigation ditch will discharge water during large floods; these openings are so designed that the combined outflow under the assumed extreme flood conditions will not exceed 100,000 sec.-ft. The spillway, provided as a precaution to insure absolute safety to the structure in case of a flood beyond the limits of probability, will be built on the solid sandstone formation.

Other Possible Plans—Other plans of flood control included relocations of the channel, complete diversion, combinations of channel improvement and a reservoir control, a single large retarding dam at Rock Canyon, a system of small reservoirs on tributaries, a 500-ft. channel along the bluffs with extensive improvement to railroad facilities, and a large parked floodway south of the river with a high levee along the north bank of the present channel. Excessive cost, physical difficulties of construction, and inability of the railroads to co-operate in financing extensive improvements to their present facilities, eliminated these plans in favor of the one adopted.

The adopted plan is ample for the conditions of any storm rainfall on record in Colorado or any adjoining state. If during the next hundred years a storm should occur anywhere within 500 miles of Pueblo which would indicate that a greater storm might occur than is provided for, the protection works could readily be

enlarged to meet such conditions. The works will handle a comparatively long-drawn-out flood, such as might result from sudden melting of snow under rare conditions, by the capacity of the improved channel, and a very sharp, sudden flood, such as might be caused by the breaking of a dam at some irrigation reservoir, by the barrier. Any existing or probable future dam above Pueblo could break suddenly without harm to the City.

Present Status—Preliminary investigations and surveys for the project were begun by the Dayton Morgan Engineering Co. in September, 1921. The Colorado Conservancy Act, which provides the necessary legal machinery for carrying out the undertaking, was passed by a special session of the legislature in April, 1922. The Pueblo Conservancy District was established under this act in September of the same year.

The Pueblo project is the second large flood-control undertaking to be carried out under a conservancy law in this country, the Miami system of Ohio being the first. The successful organization and prosecution of these projects thoroughly demonstrates the workability of this type of legal procedure for handling such undertakings. The first conservancy law was the Ohio Act, passed in 1914. It was originally drafted by Arthur E. Morgan and combines the results of practical engineering experience with legal conformity in such a degree as to make it more generally useful for conservation and flood-control projects than many of the state drainage laws or similar previous legislation. The Colorado Conservancy Act is modeled after the Ohio Act.

Quantities and Cost—The project involved the following physical quantities:

Channel excavation	999,000 cu.yd.
River levee	450,000 cu.yd.
Miscellaneous embankment	134,000 cu.yd.
Earth in barrier	217,700 cu.yd.
Earth in r.r. yards	516,000 cu.yd.
Concrete in barrier	7,200 cu.yd.
Concrete in bridges, walls and revetment	42,850 cu.yd.
Bridge steel	2,915 tons
New tracks and yards	35 miles

Its cost is estimated at \$4,000,000. It will be paid for by assessments on the benefited properties and interests, distributed over a term of years. Funds for construction will be available at once, however, through bonds of the district, issued on the credit of the appraisal roll when approved by the Conservancy Court.

Motor Car Service on B. & M. R.R.

Possibilities of motor-car service on branch lines are mentioned in the annual report of the Boston & Maine R.R. as follows:

The management has been in touch with the experiments made on various roads with gasoline motor cars adapted for branch line service. It has also conducted experiments on local branch lines with a steam unit car. These trials, although generally successful from a mechanical standpoint, have been interrupted for operating reasons and have not yet been conclusive. They have demonstrated that the field for such a type of car may be overestimated, as many branch-line runs are so involved with main-line runs or with freight, express and milk traffic that it is not possible to substitute single unit cars. It is evident, however, that as soon as a satisfactory car has been developed, it can be used to advantage at a number of points on the Boston & Maine, and this development is receiving the careful consideration of the management.

A Discussion on the Behavior of Concrete

Observations on the Service Record of Concrete Structures Under Varying Conditions With Suggestions As To the Lines For Future Study

At the annual meeting of the American Society for Testing Materials, the evening of June 29 was devoted to a discussion entitled "What Properties of and Methods of Making Concrete Require Further Investigation," with a subtitle note to the effect that it was intended to be a

"discussion of the requirements of concrete to meet the many varieties of service conditions;—what can be learned from behavior of actual structures?" There is given here an abstract of the printed papers and some notes, not necessarily quotations from the oral discussion.

Introduction

BY FRANK C. WIGHT

Managing Editor, *Engineering News-Record*

THIS is a stock-taking discussion. It is an attempt to get away from the view of concrete as a combination of cement, sand, stone and water which possesses certain physical properties to be studied and to look at it in detached fashion as a material to perform a service.

This behavior of actual concrete structures has seemed to the Society's Committee on Papers to be of exceptional interest in the study of concrete as a material. Inductive tests and studies have led to a number of theories and principles of the manufacture and placing of concrete, the best of which are embodied in modern practice. It is believed that adherence to these principles will result in a stronger and more lasting concrete, but unfortunately only time can tell whether this is a fact, always assuming that there is no readily discoverable dead line in quality, above which concrete will be everlasting and below which it will be of the most temporary nature. Five years from now possibly, better ten or fifteen years from now, we can observe concrete structures placed under recorded conditions and check up on the principles that governed their manufacture. One purpose of the present discussion is to move the clock back ten or fifteen years, to attempt to discover from the behavior of existing structures of that or greater age what were the properties and methods of making that affected their present known condition, be it good or bad.

It is recognized that this will not lead to a complete answer to the question "How can we make the perfect concrete?" It is recognized that conditions ten or fifteen years back are hard to discover, and that the elements entering into both manufacture and wear are many and diverse and that deductions made from the discoverable data are not incontrovertible. But it is hoped that by building up enough data there may appear some common facts which can be related to common results and which will be useful in the development of future practice.

The scheme of the discussion is first to consider the constituents of concrete and its methods of making, in the light of the service requirements, to discover if possible wherein lie future possibilities in cement, aggregates and proportioning and mixing. This is to be followed by a study of service conditions in roads, in sea water, in alkali water, and under the normal attacks of weather, tying up the behavior in so far as possible to the kind of concrete actually placed.

Future Requirements of Cement

BY P. H. BATES

U. S. Bureau of Standards

PORTLAND cement must have certain properties to meet certain service conditions. We are going to condense these to three conditions under which resulting cement products will be used; namely,

Class I.—Those atmospheric conditions in which the product will not be subjected to actual contact with

water after making, but be subjected to only the water vapor present in the air. In this class of products we have reinforced-concrete buildings and mortars used on the interior of structures, especially as the top coat of floors.

Class II.—Those conditions in which the product is subjected continuously or intermittently to contact with water of a fair purity or low in solids composed largely of sulfates. In this class we find the greater use of cement, for it comprises such uses as in roads, mass concrete, stuccos, sewers, drain tile, etc.

Class III.—Those conditions in which the product is subjected to the action of a solution of salts, especially sulfates. In this class appear concrete used in sea water and concrete used in those arid regions where the soils contain considerable amounts of sulfate salts, as our "white alkali" regions of the West.

Stone is not permanent. Any geologist will tell us that our kaolins are disintegrated granites and that water in certain places is very "hard" because of dissolved limestone. Hence, in cement and its products we are only properly concerned with a relatively permanent material—but a material which will give such adequate service, be it months or years, as coupled with its cost of installation and superiority of resulting product will justify its use.

Atmospheric Exposure.—The uses indicated in our Class I may seem to be the least severe of those to which cement may be placed. But even if such is the case, it is quite evident that we are in need of much research before we have the ideal cement for such purposes. Flexibility in the use of cement entails the use of more water than we should use and consequently in certain ways—strength and shrinkage—produces an inferior product, although in other ways it is superior. But what has been done so far as the cement is concerned, to develop a cement which would possess a minimum strength reduction and a minimum increase in shrinkage with the use of increased amounts of water? We have not made any thorough or even preliminary investigation to see how the different brands of cement vary in these respects. It is now time to investigate the quality of brands exhaustively, as a preliminary step in a research tending toward developing a cement affected in the least by the use of large quantities of water.

Very closely connected with the question of excess water used to produce readily flowing concrete is that of a more "workable" one obtained without the use of water in excess or admixtures of any kind. But how many researches have we in which it has been attempted to find if we have any cements more strikingly "plastic" than the others?

All floor finishers will say that with all cements there are occasions when a non-dusting, non-cracking floor is obtained and that with certain brands the likelihood of obtaining a good floor is far greater than with others. But they are seldom sure when the desired result will be obtained, and no one has developed a test or tests that will predict this quality. A research that would show just what constituent or combination of constituents in the cement, or what phenomena in the reaction of water on these, or what physical properties of the cement, as hardness of particles or fineness of grain, produce the expected and hoped-for result, would not only enable cement to

regain a favor that it has lost in this use but would also reduce the cost of floors and materially increase the use of portland cement for such purposes.

It is believed also that this same research would solve the problem confronting road builders where or when a very low atmospheric humidity exists. A number of instances of trouble have been reported of roads cracking under these conditions before final set has been obtained—and the trouble has not been due to excess water or poor choice of aggregate or poor grading of aggregate. *The difficulty has been with the cement.* Here again our tests are at fault. We store all test pieces of cement under close to saturated humidity conditions before and during the time of set. But much cement has to set in an atmosphere under considerably less than 50 per cent relative humidity and cannot be protected from evaporation during this period.

It has been our duty to examine the veneering of a large number of steel and concrete frame structures and we have been surprised at the relatively larger numbers of failures of the veneer on the concrete than on the steel structures. Architectural terra cotta, stone, and brick veneer show failures of a type that lead almost conclusively to the deduction that the concrete by contracting has induced strains in the veneer that have crushed it, especially when setting of the latter has been faulty due to the lack of fully embedding the individual units in the mortar.

Our present "soundness" tests are supposed to determine "constancy of volume," but this is only very relative and not near to the degree of accuracy that we must have and will ultimately have for certain types of work.

Moist Exposure—A road saturated with water may freeze and in this condition be subjected to the action of a warm sun on one side while the other remains well below freezing. A sewer is subjected to the action of water at practically all times and yet somewhat more than 50 per cent of the cement is soluble in water. A thoroughly dry stucco may suddenly be subjected to a heavy or long rain and while saturated be frozen.

Note that the conditions here are somewhat different from those existing in the first class. It is assuming rather much to infer that a cement which will be successful under the first condition will necessarily be just as successful under the second. That we do need studies for making cement still more adaptable is realized when we examine roads or massive retaining walls or foundations or stuccos. We are confronted often with a large number of shrinkage cracks which furnish a very unsightly appearance and would seem to mark a condition which may be conducive to ultimate failure. This condition occurs even under the most careful cases of application so frequently that it must be considered as produced by some inherent quality of the cement.

Our "standard" tests for cement will not tell the whole story. The character of the grading of the aggregates and strength tests of the concrete are also insufficient. Our present methods only very roughly approximately enable us to predict the suitability of a concrete for any particular use.

Concrete through which water constantly percolates is doomed, but only locally at that point where the percolation takes place. Hydrated cement, the matrix of concrete, is just as soluble as limestone, in fact it is more soluble. It has been found by sad experience that water must be kept out of concrete and it is being done on all large jobs. With the prevention of the water percolating through the concrete, the latter is giving adequate service. But cement in itself can not be so changed as to make the concrete impermeable. Here is a condition which requires the joint proper use of all the ingredients of concrete, cement, aggregate and water, and when so used an impermeable concrete can be obtained.

Saline Exposure—Concrete when subjected to the action of the solution of certain salts, especially sulfates, has been found to give a service which has been adversely

criticised. Yet it gives a far greater service and return on the investment of installation than any other material that might be substituted for it at less, equal or greater cost.

Again we feel that the major part of such studies must be confined to the cement. If we have a matrix unaffected or but very slightly affected by these solutions, then we must of necessity assume that we would have reached the ideal condition or at least have it in sight. For we now know enough about the quality and the grading of aggregates needed for such work to be able to make the proper choice in this respect without further study. But we have such a meager amount of information in regard to the resisting qualities of cement to such salt action that this field of study may be considered a virgin one. However, we must start not with the cement as it reaches the market, but go to the plant and still further to the quarry. We must know its entire history just as much as we must know the entire history of the concrete—assuming as is generally but erroneously done that the history of concrete starts with the delivery of the cement and aggregates to the job. We must know not only that it is a certain brand made at a certain plant but we must also know from actual observation how and from what it was made and this detailed knowledge must be obtained by some keen observer more skilled in making such observations than in making cement.

We must have tests of the cement which will give us values which are indicative of the different behaviors which cement reveals in service. However, when we have all these data we are only in the position to make concrete and feel assured that we have on file some observations which have in other cases been overlooked but which are essential. In the meantime investigations must be under way which will have for their purpose the determination of the course and the products of the reaction which takes place between the constituents of cement and water, how these are affected by the various solutions with which cement may come in contact and how the reaction may be affected by various proportions of the constituents or by the different physical characteristics under which they may exist.

There is no question but that a deductive study of concrete forces us eventually to conclude that we are grossly ignorant of cement; what it is as produced on a plant scale; what variations in ultimate quality we must expect in any plant's production from day to day; what is the nature of the reaction with water and how this reaction will deport itself in a variety of atmospheres and solutions. Some intensive work must be done that will solve these questions and enable us to produce the exact kind of cement we want at any time after having found out the kind of cement we must have for the case in question.

Those but casually acquainted with the industry are surprised that a product made to meet our present standards can be produced under such a set of widely varying plant procedures and equipment as now used. Though the product may be "standardized" it is quite evident that its methods of production are not. While it is generally believed that this wide latitude in methods does produce the same character of product, we are not convinced that such is the case, especially in view of the incompleteness of the methods used in examining the marketed product. At the present time the only incentive for study is the matter of needed economies in production, and the limited studies already made have shown the economic value of certain changes in methods—as the waste heat boiler. Furthermore, in this case it seems reasonable to believe that the required care demanded of the kiln operator, in order to insure a uniform delivery of heat to the boiler, has produced a change in the cement, more marked than is generally realized. Studies of the efficiency of the grinding apparatus, not only as to the relative operating costs of the several types of machines available, but extended, as they should be, to the efficiency of the resulting cements, would be of extreme value to both consumer and producer. How interesting would be an investigation on the properties of the resulting

cements in which the sole variable in the methods of production would be the use of wet or dry raw mixes! Fuel economy demands a thorough study of all available types of kilns and furnaces and of necessity such a study must include the question of the quality of the cement produced. May not such studies result in our specifying what methods of production are desired in addition to the physical properties, just as we now specify steel of certain physical properties made by open-hearth or bessemer process?

* * *

Proportioning and Mixing

By R. B. YOUNG

Hydro-Electric Power Commission of Ontario

UNDER certain conditions, concrete mixtures can be designed by new methods of determining proportions to give the strengths sought. Under other conditions equally likely to be met with on the job, the methods will not give the results required.

More exact methods for measuring the raw materials of concrete on the job can be studied to advantage. Under average conditions, our present methods of measuring concrete materials, particularly in the case of fine aggregate, result in lack of uniformity in the concrete mixtures, and their inherent errors tend to produce undersanded and permeable concrete more susceptible to the action of destructive agencies such as frost, alkali or sea water. Present methods are also responsible for a great many cases where contractors have overrun their estimates for cement. A 10 to 15 per cent increase in cement requirements brought about by improper measurement of fine aggregate is not unusual.

Nor do we know all there is to be known about the laws governing mixing. The relationship between the time during which a concrete is mixed and its strength at a given period is fairly well established, but little is known as to the relative effectiveness of different mechanical mixers.

What do we know about the influence of plant layout and construction on proportioning and mixing concrete? For example, the arrangement of bin gates in stationary plants influences the absolute volume of aggregate in a measured volume, and this in turn influences the cement content and water requirements and thus the quality of the concrete. Again, with the proper consistency there seems to be a remixing action during the transfer of concrete through chutes. How much do we know about this? Are our methods of charging a mixer altogether satisfactory? They are, probably, when we consider only our present equipment; but equipment could be modified if experiments demonstrated that other methods gave better concrete or were more economical in materials and power.

Concrete Exposed to Atmosphere

By P. J. FREEMAN

Consulting Engineer, Pittsburgh

ACAREFUL study of many concrete structures which have deteriorated under atmospheric conditions has led the writer to believe that most of the trouble could have been avoided if the engineers and contractors had drawn their specifications and handled the construction so that the concrete produced had the qualities necessary to meet the demands of that particular service. Instead of doing this, the required strength was used as the principal guide and little or no thought was given to other requirements, particularly impermeability, but it was assumed that any concrete having sufficient strength for the purpose would also be durable, regardless of the conditions to which the concrete was exposed.

Numerous examples could be cited, but one or two will serve to illustrate the point which the writer wishes to make.

A concrete dry-dock on one of our northern lakes was constructed at a cost of about a million dollars, using a mixture of one part of portland cement, three parts of sand and five parts of limestone. At the end of five years the

inside or exposed surface began to disintegrate so badly that at the end of about six years at least thirty per cent of the entire inside surface had crumbled and spalled away to depths varying from one to six or eight inches. Horizontal cores were drilled from the walls, which were thirteen feet thick. An examination of these cores showed that, extending in for several inches from the exposed surface, the concrete was mostly sand and cement. In placing the concrete, care had not been exercised to make an impermeable surface, although the compressive strength of the concrete was entirely adequate for the load requirements. The alternate filling and emptying of the dock caused water to percolate into the porous or permeable concrete and the action of the weather, particularly freezing and thawing, produced the disintegration which continued to eat away the walls until extensive repairs were made. The outside of the dock had been back-filled with loose material, principally cinders, which permitted water to come in contact with the wall within a few feet of the top. Excavations to remove this back-fill were made and in no instance was any disintegration found, as the wall had been protected from freezing by the fill.

A similar example shows quite clearly the results of neglecting to consider impermeability as an important factor in the design of a large hydro-electric plant. The project was started about 1912 and after building part of the dam the project was abandoned until recently. The mixtures used were 1:2:4 and 1:3:6 of portland cement, river sand, and river gravel. The 1:2:4 mix does not show signs of serious disintegration, but the concrete of the leaner mixture is in very bad condition. The investigation has not been completed, but it seems to be another case of not having the concrete made to suit the particular class of service but designed only to furnish the required strength on the assumption that such concrete would be durable.

It is not necessary to discuss the effects of placing concrete in cold weather, except to observe that many jobs are spoiled because those in charge neglect to consider that concrete must be warm to set and that they have not satisfied this requirement by merely keeping the materials from freezing while being mixed and placed and for a short time afterward. A \$300,000 reinforced-concrete building was built last winter under these conditions and when the first warm day came the concrete began to go to pieces, and it is doubtful if satisfactory repairs can be made to save the structure.

An entirely different kind of trouble was experienced in connection with the base of a concrete highway. The mixture used was one part of portland cement, three parts of river sand, and six parts of river gravel, which were tested and passed by the State Highway Department. The concrete was placed during the summer months and allowed to harden before the asphalt top was applied. After about two years it was necessary to make some repairs and it was found that the concrete was not firm and hard but could be easily broken up, and that the gravel was covered with a white deposit of calcium sulfate. After exposure to the air the concrete had a tendency to become hard. Inasmuch as all of the materials had been found to comply with the best modern specifications and chemical analyses of the concrete showed that the mixture was 1:3:6 as specified, it was not possible to draw definite conclusions and a more thorough study should be made of similar conditions with particular reference to the specifications covering the richness of the mix.

In every case the concrete disintegration mentioned, the cement was all tested and complied with the specifications of the American Society for Testing Materials.

Designers of concrete should realize that they must consider the atmospheric conditions to which the concrete will be subjected and eliminate from their design any features which would tend to cause or permit water to percolate into the concrete.

At the present time it is almost impossible to obtain the facts necessary to make a satisfactory investigation of any concrete structure that was built a few years ago.

If concrete producers will make more careful records and tests and exchange ideas concerning their troubles, the writer feels that it will take only a few years to eliminate most of the unsatisfactory conditions which now exist.

Concrete in Roads

By A. T. GOLDBECK

U. S. Bureau of Public Roads

It is difficult to conceive of any type of concrete structure which is subjected to a more complex set of influences than is a concrete road surfacing. Investigations of the past few years are just beginning to show us something of the stresses to which concrete roads are subjected by the many kinds of forces acting upon them.

The concrete is "cured" by the use of some means for keeping the surface wet, such as frequent sprinkling and with the use of a wet earth covering by ponding, by straw covering, and in the last few years by a sprinkling of calcium chloride which acts as a hygroscopic material. After a short period of curing, the moisture is allowed to dry out from the concrete, and, as has been well established, shrinkage now takes place and the concrete slab by contraction slowly moves over the subgrade. The forces of friction thus developed between the subgrade and the slab produce tensile stress in the concrete, and when this stress exceeds the tensile strength, transverse cracks form at frequent intervals. Changes in temperature of the slab also expand and contract it and cause it to slide over the subgrade, again producing compressive or tensile stress in the slab. During the day, the top surface is heated by the sun to a higher temperature than the bottom surface and naturally the slab is warped downward at the edges and corners. During the night the reverse is true; the corners warp upward. In many cases they actually leave the subgrade. During periods of dry weather, the top surface becomes quite dry, while the bottom surface is in contact with the more or less moist subgrade. Under such conditions the concrete might be warped and bent upward at the sides and ends. In the meantime the varying moisture conditions in the subgrade are swelling and shrinking the soil in a most non-uniform manner and the road is offered non-uniform support. When cold weather comes, the ground freezes. Very naturally the entire road is raised due to the expanding action of the frost, and if it happens that snow is cleared from the center of the road and is heaped up along the sides, the insulating blanket of snow prevents as deep a penetration of frost at the sides as at the center. The center of the road is then heaved more than the sides which then overhang their center support like two cantilever beams, and through overstress thus created, the slab is cracked down the center. Frost action within the concrete itself also must be resisted, and this requires a dense, strong concrete of low absorption. A number of natural influences then have been at work even before traffic is turned onto the road.

The heavy fast-moving loads of the present day produce high stress in concrete slabs under certain conditions. This is especially so with heavy fast-moving vehicles having well-worn solid rubber tires. Impact stresses are apt to be high and this is especially true in the vicinity of joints and on roughly finished spots in the road. Not only does this heavy impact produce high bending stress, but the local pressure on the immediate surface is considerable. There are concrete roads in which exceptionally poor coarse aggregates have been used largely as a matter of expediency, which are now showing signs of distress from the action of traffic.

When we add to all of these influences the troubles which are apt to occur due to the use of unsuitable materials, too much water, or greatly inferior workmanship, coupled with a design ill-adapted to the conditions of subgrade and traffic, the wonder is that concrete roads are capable of giving the most excellent service which, in general, they are giving under our present-day rubber-tired traffic.

Defective Design—The concrete road has had its share

of failures due to the use of a design which has been ill-fitted for the traffic and subgrade conditions. There have been reasons for poor design in the past, for many principles are only now beginning to be recognized and understood, and moreover, our oldest concrete roads have witnessed an increase in variety and intensity of traffic such as has never been recorded in a similar period in history. Again, the phenomena in connection with the movement and accumulation of moisture in the subgrade and the action of moisture on various kinds of subgrade materials have never been given thorough study.

Defects Other Than Design—There are other defects occurring in concrete roads, some of which are of no particular importance, and others of which are quite serious. These defects as observed by the District Engineers of the U. S. Bureau of Public Roads, by their assistants and by the author are listed as follows:

1. Cracking:
 - (a) Transverse;
 - (b) Longitudinal;
 - (c) Diagonal cracking;
 - (d) Corner cracking;
2. Hair Checking of the Concrete Surface.
3. Surface Irregularities in the Pavement as Constructed:
 - (a) Due to lack of uniform consistency of the mix;
 - (b) High joints;
 - (c) Slumping of concrete on grades;
 - (d) Unevenness of side forms.
4. Settlement of the Pavement.
5. "Blow-ups" of the Pavement.
6. Slipping of Joints.
7. Spalling at Concealed Joints.
8. Surface Scaling:
 - (a) Due to fine aggregate;
 - (b) Too wet a mixture or excessive finishing;
 - (c) Calcium chloride curing.
9. Surface Ravelling.
10. Surface Wear.
11. Concrete Disintegration:
 - (a) Due to alkali;
 - (b) Defective materials.
12. Surface Pockets:
 - (a) Due to dirty aggregate, balls of clay, coal, wood chips, soft material.

Summary—With the possible exception of cracking, there is hardly a defect listed and described above which cannot be almost entirely eliminated from concrete roads through the use of proper design and construction methods, satisfactory materials and their intelligent combination.

Concrete for pavements must have high flexural and tensile strength in order to minimize the frequency of cracking, it must have high density to better enable it to exclude moisture; the aggregates must be well bonded together to resist the disintegrating action of traffic, and the mixture must be homogeneous in proportions and consistency.

Perfect concrete road building is an intricate operation which too often is entirely under the control of inspectors who are not well versed in the technique of materials or construction. They do not understand the great importance of careful attention to details. By all means, concrete road inspectors and, in fact, inspectors on other types of concrete construction should be schooled in the causes and effects in connection with the various operations under their control. It is absurd that millions of dollars worth of materials and expensive construction should be left at the mercy of any but the most competent of inspectors.

Exposure to Sea Water

By S. C. HOLLISTER

Engineer, Philadelphia, Pa.

Of the many structures of plain or reinforced concrete exposed directly to sea water for the past ten years, few are free from some degree of deterioration.

The nature of the deterioration of plain and reinforced concrete by exposure to sea water is distinctly divided into two classes: (1) The deterioration resulting from the corrosion of the reinforcement, and (2) the disintegration under certain conditions of the concrete itself. Both forms are found only above the level of complete immersion. Attack is found regardless of whether sea or fresh water was used for gaging; whether the structure was cast in place or formed of precast units; or whether construction proceeded in the open air or under water. The deterioration seems to bear little relation to the variety of mixtures usually employed in construction work. Faulty placing or excessively wet mixture, however, hastens the attack.

The attack on reinforced concrete begins with the corrosion of the reinforcement. No corrosion is found where

there is complete immersion. It begins just above the mean water level, in from two to five years after construction. A two-inch covering of 1:2½:5 mixture or richer will protect the reinforcement from corrosion by fresh water; but no concrete mixture in this thickness will protect the steel from sea water corrosion.

Due to the expansion accompanying corrosion, the concrete covering is split in the direction of the reinforcement. These cracks permit more ready ingress of the sea water and the attack proceeds with increasing rapidity. Splitting does not extend below low tide to any great extent, because corrosion does not take place there; instead, it progresses upward, not only within the wave or spray belt, but as far as salt-laden air is found. A satisfactory permanent protective coating for the steel which does not seriously reduce the bond has not yet been found.

Once a portion of the surface of the concrete has been spalled off, the sea water attacks the concrete mass in the same manner as in plain concrete structures.

The attack on plain concrete begins at the mean water line and extends in diminishing degree upward and downward from that level. It originates wherever the sea water can gain access to that portion of the concrete mass lying within the surface skin originally formed over the exterior of the structure. Sometimes this access is provided through a honey-comb, or through a layer or pocket of laitance; at other times it is provided through the removal of the surface skin by abrasion or frost action.

Once the sea water has reached the inner concrete, chemical disintegration of the cement develops. The matrix is softened in time to such an extent that the concrete can be scooped out with the hand. Magnesium chloride, and especially magnesium sulphate, in the sea water appear to be the principal agents of attack. Calcium sulphate in considerable quantity is formed; and this compound having no setting properties under the conditions, the mass may be washed away by stream or wave action. Mechanical abrasion and frost action hasten disintegration.

Chemical disintegration begins at once after the inner concrete is reached by the sea water. Marked disintegration has been noted in two years where honey-comb or laitance forms the path of communication. Carefully made structures two years old, so situated as to be subject to abrasion by floating ice, have shown well-started attack. In some cases, the concrete has been wasted away for a depth of from eighteen inches to two feet on structures eight to ten years old.

To date, little has been learned of a constructive nature concerning the arrest or prevention of this wide-spread attack on concrete marine structures, other than to armour them with treated timber, stone or paving brick. Little is accurately known of the chemistry of the concrete disintegration. Cements other than portland are advanced for marine use; but although each may have some instances of successful use, there is no well-defined conclusion of preference over portland cement. The lack of thorough understanding of all cements is a handicap in the solution of the problem.

Mass Concrete in Service

BY ARTHUR P. DAVIS

Recently Director, U. S. Reclamation Service

THE writer has had opportunity to examine many large masses of concrete such as dams and bridge abutments, either in a supervisory or consulting capacity, or as an observer during and after construction.

These observations are very convincing upon two points:

1. That where clear water can be made to glide over concrete without disturbing its velocity or abruptly changing its direction, there is no practical limit to the velocities that can be permitted without harm.

2. That concrete which is subjected to the impact of water under high velocity is rapidly eroded and that under such conditions the velocities must be very carefully limited.

Water carrying sand or grit will gradually erode good concrete if the velocity is high.

Exposure to Alkali

BY G. M. WILLIAMS
University of Saskatchewan

IN numerous instances, irrigation structures, foundations and other concrete works have shown signs of failure after short exposure to the salts in the soil. Various theories as to the cause of deterioration were advanced and it was first believed to be due to the crystallization of the soluble salts in the pore space of the concrete, which action was greatly accelerated by the use of poor aggregate and poor methods of preparation and curing. The problem was further complicated by the fact that not all concretes exposed to apparently similar conditions were attacked, tending to substantiate the theory that aggregates and workmanship were to blame. The possibility that the deterioration was primarily due to reaction between the salts in solution and constituents of the cement was also advanced but was not generally accepted owing to lack of experimental verification and the knowledge that materials and workmanship were of inferior quality in some cases.

Deterioration due to alkali has generally occurred in the arid or semi-arid sections of the Western states. The weathering and breaking down of rocks by long exposure to the elements has resulted in the formation of soil, and the salts of sodium, calcium and magnesium which were once among the constituents of the rocks are now found distributed throughout the soil, usually in greatest amount in the clays and shales. While most ground waters carry in solution appreciable quantities of one or more of these salts, it is in the arid regions that concentrations are sufficiently high to result in such waters being classed as alkali waters. In the humid region, heavy rainfall for many years has washed most of these salts from the soil, but in the arid and semi-arid districts, a smaller rainfall together with soils less easily drained have resulted in the conditions as now found. The excessive application of irrigation water, together with poor drainage facilities, has resulted in a gradual raising of the soil-water level which has brought about a high concentration of salts at the ground surface and a few feet below.

Investigations to study the cause of deterioration were started in those localities where the trouble was first encountered.

All of the investigations may be considered as establishing the first phase of the investigation—definitely fixing the problem—and demonstrating the fact that disintegration is primarily a chemical action, rather than a physical disruption, and indicating the variable factors and conditions which must be met in practical work. The second phase of the work involves the discovery of means, materials and methods for eliminating the possibility of disintegration in future work.

1. In many districts of the Western states and Canada there are areas where the salt content of the soil is high and concrete cannot be used with assurance of success.

2. Study of field conditions indicates that deterioration of concrete structures is almost entirely confined to regions where the sulphate type predominates. Good quality concrete is apparently being successfully used in chloride and carbonate soils.

3. Rapidity of disintegration varies directly as the sulphate concentration.

4. Where concentrations are permanently low, good quality concrete appears to have a life which fully justifies its use.

5. Concentration of salt in ground water may be extremely variable at points short distances apart. There also appear to be seasonal or yearly variations in some districts.

6. Concrete of high quality is most resistant to action. High quality for exposure to alkaline conditions is measured by impermeability or resistance to passage of water through the mass under pressure. The one big factor necessary to secure low permeability is high cement content, so that high compressive strength can generally be

used as a criterion of low permeability. Consistency, within practical working limits, and gradation of aggregate are secondary factors in obtaining a concrete of low permeability.

7. Where alkali conditions are bad, the factor of safety against failure can be greatly increased by employing proper drainage precautions.

8. The employment of a membrane waterproofing may prevent action for a time at least, but such a method is not practicable under all conditions.

9. Portland cement, as now constituted, is inherently subject to attack by sulphates in the soil and ground water and the practical and final settlement of the alkali-concrete problem is dependent upon modification of, or the discovery of some material which may be added to, portland cement to make it immune to such action.

Oral Discussion

Duff A. Abrams, Structural Materials Testing Laboratory—The strength and resistance of concrete depends mainly on the water-cement ratio and not on the aggregate. Aggregate must be well graded, clean and structurally sound. Given that a strong and durable concrete can be made provided methods of manufacture are correct.

H. S. Spackman, Philadelphia—No encouragement is given to the manufacturer of cement to strike out on new lines so long as the user does not call for other than standardized cement. The user must be educated to his own needs in this respect. Portland cement is far from perfect. The durability of concrete depends largely on the binder cement because the aggregate when properly selected is quite permanent.

Robert W. Lesley, Philadelphia—From long experience in the manufacture of cement, particularly in the early days when more than fifty-seven varieties were made, it seems strange to hear suggested a reversal of the one standard toward the getting of which so much effort was expended.

W. F. Purington, New Hampshire State Highway Department—Study must be made of aggregate. In New England particularly there is danger from feldspathic sands which are in process of decomposition. Much of this type of sand, however, is used in concrete. It is initially weak and there may be progressive disintegration. Furthermore, shape of sand is a factor of strength. Slaty or ferruginous schists are stronger than granular sands. This may be because the fibrous material interlocks. Microscopic study of sand is most necessary in determining strength.

R. W. Cram, Purdue University—The methods of manufacturing concrete should be studied. There is need for extensive research into fabricating methods. The art of placing is far behind the science of design. Unquestionably with this, too, should go more study of cement.

T. G. Campbell, J. N. Chester Engineers, Pittsburgh—Cited several cases of disintegrated concrete in bridge floors, filtration plants, etc. His firm feels it cannot prophesy that concrete will not deteriorate.

W. C. Hart, Portland Cement Association—Principal difficulty with outdoor concrete is the excessive use of water. There is evidence in study of existing structures that those built before the water transportation method of placing concrete were developed are in good condition. Numerous structures have been examined, particularly the Illinois Central bridges built in 1902 and the Illinois-Mississippi Canal structures built in 1893. All of these show excellent present condition. Danger today is the use of too much water and lack of proper curing. Most careful inspection is necessary.

R. S. Greenman, New York State Engineer Department—What is needed is production of a non-absorbent concrete. Concrete which will best resist frost action is the most permanent. Density of concrete will not always keep out water, because dense concrete may contain aggregate which is porous. Copings are the weak points in most concrete buildings. Why do they disintegrate? Because

practice allows the poorest concrete to flow to the top or sides with no compactness.

J. J. Payne, City Testing Laboratory, Pittsburgh—Many bad cases of concrete street base failures in Pittsburgh. Investigations have not fully revealed the trouble. The practice of concreting is far ahead of the theory. It will not hurt to study it.

W. G. Atwood, Marine Piling Investigation—If we can make a stable cement and make a good concrete later from the cement the problem of concrete in sea water is solved. Portland cement of today does not meet Vicat's hydraulic index for sea water written a hundred years ago.

E. E. Butterfield, Chemist, Borough of Queens, New York—Described special attention given to concrete in sea water now being placed in Jamaica Bay Boulevard. This concrete, due to special precautions, has the remarkable density of 0.875 and tests 4,200 to 6,000 lb. Hopes that it will resist sea-water attack, but is not altogether confident. There are two examples in the Borough of Queens of concrete in sea water, one carefully made, which is resisting the attack, and one poorly made, which has quite disintegrated.

H. S. Mattimore, Pennsylvania State Highway Department—We can get the most education from failures, but we make a mistake in giving brief rules for making concrete. The concrete placer himself must be educated. Materials are not being tested the way they should be in most work. We must study something besides strength. Aggregates must be studied for more than their strength.

W. M. Kinney, Portland Cement Association—The greatest trouble with concrete today is the water content. Sooner or later proportioning will be on the basis of a fourth ingredient, water added to the cement, sand, and stone which are now noted in ingredients. Failures of concrete observed are mostly in surfaces and in appearance. The structures are still quite capable of sustaining the loads for which they were designed and for which they are used. A suggestion for various standards of cement would bring back the old days of the cement business which were economically unsatisfactory. With the great number of cement plants designed so as to reduce as low as possible the freight distribution of cement, there would be the greatest difficulty in manufacturing different kinds of cement, certainly not justified if the present cement will serve. So far nothing has been developed to show that the present method is not satisfactory. In construction the placing in the forms is the detail most neglected and the actual fabrication must be perfected in a wide degree.

R. L. Bertin, White Construction Co., New York—There are plenty of good rules for making concrete. The trouble is they are not observed. If the studies on concrete and the methods of making it could be enforced we would have less trouble.

R. J. Wig, Los Angeles, Calif.—There is little danger of plain concrete in sea water so long as full attention is paid to its constituents and manufacture. Reinforced concrete in sea water is a different matter, though with proper design the deterioration in the slender type of members even may be reduced, if not eliminated.

Ernest Ashton, Lehigh Portland Cement Co.—Attention should be called to the fact that the present activity in the study of concrete has been brought about most by the activities of the manufacturers who went far beyond the manufacture of the cement itself into a study of the concrete in order to perfect the material which the cement is used in. So far the manufacturers have been anxious to establish a standard for cement so they might know what they are making and devote their attention to making the one thing. This standard having been established and the methods of testing it having been established, they are now ready to enter into a more detailed investigation of the nature of cement and the method of improving it. Such studies are going on and it is hoped will result in some material benefit to cement users. These users should bear with the manufacturers during this study period. The problem is not simple and the solution is being honestly sought.

Building Intercepting Sewers and Siphon at Hammond, Ind.

Large Concrete Pipe in Deep Trench—Well-Points Drain Sand—Traveling Trestle Handles Excavation and Backfill

BY J. B. MURPHY

Engineer of Construction, Sewer Department, Hammond, Ind.

IN CONSTRUCTING a system of intercepting sewers at Hammond, Ind., features of special interest were the use of concrete pipe up to 9 ft. in diameter, well-points and pumps to drain the deep bed of water-bearing sand in which the sewers are laid, a trestle and cable-haulage system for handling the excavated material and backfilling, and the construction of a double-barrel siphon under the river. The construction plant and methods are shown in Figs. 1 and 3.

In the summer of 1922 contracts were awarded for the construction of the main intercepting sewers and pumping station of the new sewerage system, which

FIG. 1—CRANE PLACING 84-IN. CONCRETE PIPE

is of the combined type and will provide drainage for 4,680 acres or for all of the city except a portion recently annexed on the south side and that part near Lake Michigan called Robertsdale. The city is divided by the Grand Calumet River, necessitating the construction of two general sewer systems, each with an intercepting sewer and both interceptors delivering to one pumping station, from which the sewage is discharged into the Calumet River. There are about 6½ miles of intercepting sewer ranging from 24 to 108 in.

On the south side, the intercepting sewer varies from 54 to 108 in. internal diameter, and is connected to the pumping station on the north side by an inverted siphon consisting of two 60-in. reinforced-concrete conduits with a total length of 300 ft. and placed 56 ft. below the surface of the river. The north side intercepting sewer varies from 24 to 84 in., internal diameter and also discharges into the wet well of the pumping sta-

FIG. 2—HEELING PIPE INTO POSITION

tion, the bottom of which is 17.95 ft. below the surface of the river. A brick and steel building 52x148 ft. houses four centrifugal pumps and has space for two additional pumps when required. Two 20-in. electrically driven pumps, each of 20 c.f.s. capacity, take care of dry-weather flow; two 48-in. gas-driven pumps, each of 100 c.f.s. capacity, provide for storm-water flow.

The average depth of the sewers is 18 ft., in fine, water-bearing sand, the elevation of the water table being approximately 4 ft. below the surface of the ground and 14 ft. above the invert of the sewers. In the north portion of the city the water table is slightly above the surface of the ground. Under these conditions and since the discharge of the entire system has to be pumped into the river, at an estimated cost of \$33 per million gallons per twenty-four hours, the question of infiltration became very important. Monolithic reinforced-concrete construction was considered in the original design for the interceptors, but it was later decided to use reinforced-concrete pipe for the following principal reasons: (1) In many sections of the country such pipe has been used successfully for conveying water under 10 to 50 lb. internal hydrostatic pressure, thus convincing the designers that its use was particularly adaptable for preventing infiltration; (2) the units can be fabricated on or near the site of the work several weeks in advance, allowing sufficient time for seasoning and affording adequate inspection before and after the units are installed.

The 108-in. pipe are 5 ft. long, with a 9-in. shell and weigh 8.6 tons each. They are installed by a 20-ton crane, as shown in Fig. 1, and the methods used in drawing them together are illustrated in Fig. 2. The units are laid to exact grade and levels taken on portions of the finished lines show that the elevation of the invert does not vary more than ¼ in., from the correct grade. Record runs of 100 ft. in eight hours were made during the extremely cold months of January, February and March, 80 to 90 ft. of 96-in. and 60 ft. of 108-in., pipe are average runs in eight hours. The lines are immediately backfilled as shown in Fig. 3. The joints are made tight by filling with neat Utica natural cement and oakum.

Rapid progress under the unfavorable conditions of soil and water have been made possible by the use of special construction methods. In order to remove the ground water from the trench, two 4-in. cast-iron pipe lines each 300 ft. in length are installed, one on each side of the trench (see Fig. 3), with gate valves 20 ft. apart on each line. At 4-ft. intervals on each line are located double hose-connections which are connected by means of 1½-in. hose, 3 ft. long, to 16 ft. lengths of

2-in. steel pipe driven vertically into the ground parallel to and outside the sheeting at 2-ft. intervals.

These drive pipes are provided with ordinary well-points 3 ft. long, which are jetted down to about 2 ft. below the invert of the sewer. The 4-in. main lines are connected across the trench by means of a 4-in. rubber hose. The ground water is removed through this system by the use of 7x8-in. triplex pumps, each fitted with vacuum gages and operating continuously, day and night. Experience has shown that it is necessary to keep the pumping system in operation for a length of trench representing a two-days' run and for 24 hours after the joints have been made so as to let the grout set. With the sand bed thus drained the working conditions at the bottom of the trench are very satisfactory.

Excavation to a depth of about 4 ft. is done by a dragline excavator and the trench is sheeted for this depth. Below this level the work is done by hand, the material being removed by a Potter plant consisting of $\frac{1}{2}$ -yd. buckets handled by a cable-operated car on a traveling steel trestle 352 ft. long, built over the trench. At the rear end of this trestle the material is dumped for backfilling.

This sewerage system was designed by W. F. Bridge, city engineer of Hammond, and by the writer, who is also in general charge of construction. The contract for the south side system and inverted siphon was let to the Proudfoot Construction Co., Chicago, which sublet the siphon work to the Subway Engineering Co., Chicago. The north side system is being built by the United Construction Co., Hammond, Ind., and the pumping station by Bates & Ahlborn, also of Hammond. The concrete pipe was made by the Independent Concrete Pipe Co., Indianapolis, Ind. The total estimated cost is \$1,497,704, divided as follows: North Side system, \$846,596; South Side system, \$345,784; inverted siphon and gates, \$78,000; pumping station, \$227,324.

Twin Tunnels for Sewer Siphon Under Calumet River

**Shaft Lining Sinks with Cutting Edge—Pneumatic Tools for Heavy Clay in 6-Ft. Tunnels
Steel and Wood Forms**

AN INVERTED siphon under the Grand Calumet River at Hammond, Ind., is required to connect the new south side intercepting sewer with the pumping station on the north side, as described in the preceding article. This siphon, shown in Fig. 2, is composed of

FIG. 1—STEEL FORMS FOR SEWER TUNNEL

FIG. 3—SEWER OF 84-IN. CONCRETE PIPE IN TRENCH

two horseshoe tunnels 5 ft. 8 in. x 6 ft., two 11½-ft. shafts concreted to form two 5-ft. tubes in each shaft, an intake and an outlet chamber and two 72-in. and two 60-in. sluice gates with operating machinery. All the excavated material was used by the city for covering the sand formation in the public park, thus forming a good base for a soil top dressing.

Shafts—The shafts were 14 ft. in outside diameter and 11½ ft. inside the concrete shell. After about 8 ft. of sand and gravel the shafts were in soft clay which soon changed to hard dry clay of a shaly character; this latter disintegrated into thin horizontal layers or flakes when brought up and exposed to the air. Several seams of water-bearing sand were encountered, but only a little pumping was required since the shafts were not pumped out until the cutting edges of the forms had penetrated about 6 ft. into the clay. The depth from grade to tunnel invert was about 60 ft.

Steel forms in 5-ft. lengths were used for the south shaft and wood sectional forms in 8-ft. lengths for the north shaft. The cutting edge in each case was an angle 4x4½ in. and a ½-in. plate 18 in. deep with 3-ft. anchor bolts spaced 24 in. c. to c. At each shaft was a traveling derrick with double-drum hoist and 40-ft. boom handling a ½-yd. clamshell bucket. The shafts were sunk by open dredging to the top of the tunnel

and were underpinned from that level to the bottom. Several small cavings or wash-ins occurred in the south shaft, owing to old bed springs and other obstructions being caught under the cutting edge and carried down with it, thus forming a path on the outside of the shell for sand and muck to follow and wash under the cutting edge. In the north shaft there was little trouble. As each 5-ft. or 8-ft. length was sunk the shell

spades or chisels were used. Muck was handled in $\frac{1}{2}$ -yd. steel dump-cars on tracks of 14-in. gage with 12-lb. rails on 4x4x30-in. ties spaced 3 ft. c. to c. These cars were handled on an elevator 5x4 $\frac{1}{2}$ ft. in the south shaft, both tunnels being driven from this shaft to within 10 ft. of the north shaft and then completed from the latter. Gravel concrete was used, of 1:2:4 mix. In cold weather, the water and sand were heated, and for the

FIG. 2—SEWER SIPHON, TWIN SHAFTS AND TUNNELS

was concreted and the concrete was allowed to set for 48 hours before the excavation was continued, the shell going down with the cutting edge.

Tunneling—Tunnel excavation was mainly in the hard blue clay, which was dry but contained some boulders and numerous pieces of shale and slate. In this material the ordinary method was to mine 6 ft. and place the concrete lining. This operation was completed in nine hours, so that with two shifts the daily progress for each tunnel was 12 ft. Several sand pockets were encountered and some of these contained water. At these points the tunnels were timbered and the mining and concreting was done in 3-ft. sections. Steel forms were used, as shown in Fig. 1, each rib consisting of two 5-in. channels for the ribs with angle-iron lugs at top and bottom. The lagging was 2x6 in. with beveled edges, and was in 6-ft. and 3-ft. lengths. Each rib was set up by means of a 3-in. wood block at the crown and another in the invert.

Grub hoes and knives were used in driving the first 30 ft. of each tunnel, after which compressed-air

shaft lining about 2 lb. of calcium chloride per bag of cement was added to hasten the setting. Cofferdams were built for the intake and outlet chambers, the water being taken care of by use of well-points and electric pumps.

Lines for the tunnels were furnished by the contractor, being transferred to the headings by means of piano wires and heavy plumb-bobs suspended in the shaft. Grades were given by the city engineer. The south shaft was begun Dec. 16, 1922, and completed Jan. 16, 1923. The intake chamber and 60 ft. of tunnel were excavated in February. In March, both tunnels were driven and concreted for 450 ft. In April, the tunnels, north shaft and outlet chamber were completed. The Subway Engineering Co., Chicago, had the sub-contract for the siphon, the general contractor for the sewer work being the Proudfoot Construction Co., Chicago. Its price was about \$77,000, including the gates.

Ernest A. Clark, member of the Subway Engineering Co., was in direct charge of the work.

To Increase Safety of Traffic on Highways

H. E. Breed Submits Recommendations in Committee Report to National Highway Traffic Association

RECOMMENDED practice to increase the safety of highway traffic, particularly at curves, was embodied in the following report submitted May 10 to the annual meeting of the National Highway Traffic Association by a committee consisting of H. Eltinge Breed, consulting highway engineer, New York City, chairman, W. G. Thompson and W. M. Acheson.

Safety on the highway is a matter of national concern. During this last year 14,000 lives have been sacrificed in automobile accidents. There are now registered in the United States 12,000,000 motor vehicles. This year's increase to that number is estimated by manufacturers at 3,000,000. The risk to safety lies in the congestion of 90 per cent of these vehicles upon 10 per cent of our roads. This risk we must minimize. That it is at present fraught with appalling loss of human life is evidenced by the casualties from automotive vehicle accidents—a loss yearly greater than by all other means of transportation combined.

The majority of these accidents of congestion occur under five conditions, all of which road builders may help to eliminate.

1. Sight distance on curves, both horizontal and vertical, which is insufficient to permit precaution against the other man's reckless driving. Lack of sight distance also increases accidents at intersecting roads and railroad crossings.

2. Insufficient width of pavement, especially in congested districts, which increases the number of cars that turn over on soft shoulders and roll down unprotected slopes. Narrow, or single-track bridges are a constant menace. In the design of roads 10 ft. should be allowed as a minimum width for each single line of traffic each way and 9 ft. more for each additional line each way.

3. The inadequate, irregular and improper spacing of danger signs which encourages a general carelessness of their import. Judged by the number of accidents in their vicinity, they are a spur to the recklessness of the joy-rider and a consequent risk to his sober brethren.

4. The tendency of detours under traffic to become almost impassable. On heavy-traveled routes traffic going in different directions should be routed over different detours, or, if detours are inadvisable on account of dangerous or impassable conditions, the road should be built horizontally a half at a time.

5. Railroad grade crossings.

Four Methods of Attack—To help prevent accidents to which these and other highway conditions are conducive, we may proceed at four points: First, to secure good design for new roads; second, to promote adequate improvement of old roads; third, to insist upon reconstruction of existing roads at places that have proven especially dangerous such as grade crossings, approaches to bridges, etc.; fourth, to improve the location of the center line on dangerous curves and elevations. Under these headings the following recommendations are made. They aim to promote the safety of the traveling public as far as impersonal factors can do it, and they aim to diminish as far as possible the personal menace projected by the reckless driver. Safety for the careful with protection from the careless.

Under the consideration of general safety for traffic comes the necessity of standard practice throughout the country in respect to placement of danger signals, elevation and banking of curves, widening and regulation of traffic on curves. Standardization in these matters is imperative because with the completion of transcontinental routes there is increasing interstate traffic. Drivers traveling to remote sections cannot be expected to apprehend distinctions in practice now existing between different highway departments, yet departure in one state from what they have

become accustomed to expect in others is a frequent cause of disaster. There is no real obstacle in the way of this standardization; it is merely a matter of agreement among state highway officials and motor organizations.

Recommendations—Your committee has amplified the resolutions that you passed last year. They now stand:

1. On all curves of more than 3 deg. the pavement and inner half of the earth shoulder should be banked. This superelevation should vary from 0 for a 3-deg. curve to 1 in. per foot of width for curves of 20 deg. or sharper.

2. On all curves of more than 4 deg. the pavement should be widened on the inside $\frac{1}{2}$ ft. for each 1 deg. increase in curvature. The widening and banking on a 4-deg. curve should start at a minimum of 50 ft. before reaching the P. C. and come to the fully widened and banked section at or very soon after reaching the P. C. Inversely, the regular section should be reached at a minimum of 50 ft. beyond the P. T.; for a 20-deg. curve, this varying or transitional width should be about 150 ft. long, with proportional lengths for intermediate curvatures.

3. A line about 4 in. in width and of an appropriate color should be painted on the center line of pavement on all curves, both vertical and horizontal, this painted line to be renewed as necessary in order to keep it conspicuous so that it may indicate to traffic in each direction the limit of its half width of pavement.

4. All sharp or dangerous curves, either simple or reverse, horizontal or vertical, should be posted about 500 ft. from each end with a sign indicating that danger exists. Railroad crossings at grade should be posted in a similar manner.

5. The National Highway Traffic Association recommends to all legislative committees preparing motor traffic laws that the attempt to pass a motor vehicle while going in the same direction on a curve, either horizontal or vertical, where the unobstructed line of vision is less than 500 ft., be made a misdemeanor; all damages resulting from an accident under these circumstances to be placed upon the passer.

6. The minimum radius of curves should be 1,000 ft. unless prevented by an approach to a bridge not practicable to change or an improvement being made on village or city street, even to the end that new right-of-way should be procured in order to increase the radius, bearing in mind that the improvement is being made for a long time, and that land values may increase to an extent that might prohibit procuring more right-of-way.

7. Providing there is sufficient space within the right-of-way, earth slopes should be carried out with a 4 on 1 slope. If this is not possible a guard rail should be placed on the inner edge of all curves of more than 8 deg. This rail should be kept painted white and be about 4 ft. in height.

8. In order to prevent the shoulders adjacent to hard-surfaced pavements from being gouged out, gravel or crushed stone, $1\frac{1}{2}$ in. and $2\frac{1}{2}$ in. size, mixed and filled with screenings, should be placed 2 ft. in width and 4 in. in depth on each side, maintained at the level of the pavement. An application of hot tar or asphalt on this gravel or stone will be found beneficial.

9. For public safety all advertising signs and obstructions along highway routes should be eliminated *except those erected by direction or permission of officials having jurisdiction over the highways and for public benefit.*

10. A definite sum should be set aside annually by each highway department, and a comprehensive plan devised on which annual progress is made, for the elimination of the most dangerous grade crossings.

11. Everyone who drives a car should be instructed by some competent person in the common courtesy usage and legal road rules.

12. There should be cleared away wherever possible all stone walls, brush, trees, banks, etc., on the inside of curves where it is impossible to obtain a sight distance of 500 ft.

13. All single-track bridges should be widened to double-track, and every community, through surveys by proper officials, should ascertain the conditions of and on its bridges to carry safely loads up to the legal limit.

14. Where conditions warrant proper sidewalk provisions should be made and where sidewalks are provided it should be a misdemeanor for pedestrians to encumber the roads.

Allocating Concrete, Cast Iron and Wood Stave in a Pipe Line

All Three Kinds Used in 18½-Mile Conduit Bringing Water to Norfolk, Va., From a New Storage Reservoir

CONNECTING the new 4-billion-gallon Lake Prince storage reservoir of the Norfolk water-works with the filtration plant of the city, is an 18½-mile conduit of 30- and 36-in. pipe line made up of 2½ miles of cast-iron pipe, 10 miles of wood-stave pipe and 6 miles of concrete pipe. Protests against the use of anything but cast-iron by citizens led the engineers to study the route of the line carefully to obtain comparative figures bearing on the financial outlay, carrying capacity, leakage and desirability. The result was that all three were used—wood-stave wherever the local conditions were entirely favorable to its durability; cast-iron where conditions were not favorable to use of wood-stave or concrete, such as a summit approaching the hydraulic grade line and at river crossings; concrete, where conditions permitted and the working head would not

WOOD-STAVE PIPE ON CONCRETE BRIDGE OVER CREEK

exceed 150 ft. In a paper presented recently before the Virginia Engineering Society, William H. Taylor, III., city engineer, gave the following analysis:

Assuming the first cost of the wood-stave pipe of the required diameter and designed for a certain pressure to be unity, then the relative cost of the reinforced-concrete and cast-iron pipe of the same diameter and designed for like pressure would be represented by about 1.7 and 2.4, respectively. Corrected for carrying capacity, leakage and durability, based to some extent on experience with a local wood-pipe line, the relative costs of 1, 1.7 and 2.4 were corrected to 1.6, 1.7 and 3.4, respectively, considering every known or estimated advantage or disadvantage possessed by any one of the three pipes over the other two. It was therefore decided to use cast-iron pipe only where it was impracticable to use either the wood-stave or concrete pipe.

On the summit referred to, and less than two miles from the dam, a surge tank 10 ft. in diameter and 125 ft. high has been built, as a vent for entrained air, a pressure regulator, and a safety device against vacuum troubles.

The supply line has comparatively few curves of any magnitude, either vertical or horizontal, but the country varies from cultivated fields to swamp land, forest and rivers. Four major streams extensively navigated were crossed by submerging the pipe, and fourteen minor waterways were crossed by exposing the pipe and supporting it upon concrete piers on piles above the stream or bog. A right-of-way 30 ft. wide has been purchased throughout the length of the line, providing the means for future development. The submerged river crossings were described in *Engineering News-Record* of Sept. 7, 1922, page 393.

Venturi meters will measure the delivery of water into the line at the dam, and out of the line at the filtration plant. Near the ends of each section of concrete pipe

LAYING CONCRETE PIPE WITH A PORTABLE GANTRY

Pipes were handled on the job by caterpillar tractor and special low-hung trailers with plenty of clearance between front and back axles to permit rolling the pipe off sideways.

brass rings 24 in. long were inserted (precast in a section of the pipe) for use as permanent pitometer stations. These rings were machined smooth and accurately calibrated. By means of pitometer readings at these points, together with accurate pressures ascertained, reliable determinations of the value of *C* in the Chezy formula are expected, as well as information as to leakage in the different kinds of pipe under service conditions. Static pressure tests indicate a leakage of 83 gal. per inch of diameter of pipe per mile per day for the concrete pipe and 310 gal. for the wood pipe.

The concrete pipe has 4-in. walls and was cast in 12-ft. lengths. Midway of the wall is a steel cylinder with electrically welded seams, riveted and lead-calked to cast-iron bell and spigot end rings. The rings were turned, a groove was provided in the bell and a taper was given to the spigot ring. A special lead ring gasket inserted in the groove was tightly compressed when the spigot end was drawn "home" beyond and over the tapered section of the spigot ring. The 2 in. of concrete outside of the steel cylinder was reinforced with woven-mesh wire.

The Redwood Manufacturing Co. of San Francisco manufactured and laid all of the wood-stave pipe. The Lock Joint Pipe Co. did likewise with the concrete pipe, and the Lynchburg Foundry Co. made the flexible joint cast-iron pipe. Col. Dabney H. Maury was consulting engineer on this work, which was designed and carried out under the general direction of the writer with Norman Z. Ball as designing engineer and David A. Decker as assistant engineer in

ELECTRICALLY WELDING A LONGITUDINAL SEAM

charge of construction of the dam and pipe line. W. R. Galt, John O. Miller and John N. Vaughan were resident engineers.

Deformations of Arched Dam Measured by Triangulation

LAST year the geodetic department of the federal survey bureau of Switzerland undertook to measure by triangulation the deformations of a small arched forebay dam. The work was done at the request of the electric traction division of the federal railways and had the main purpose of determining whether accurate and consistent results in such measurement could be obtained by survey methods. According to a report of the work in the *Schweizerische Bauzeitung* of Jan. 20, the results showed the method to be wholly successful. In fact, triangulation proved somewhat more satisfactory than direct sighting on a scale attached to the crest of the dam and read from an instrument set up

to be carried out in a single day. The results are sketched in figure herewith.

At the left the triangulated displacements of the six bolts are shown in plan. At the right are plotted the deformation profiles of the wall in vertical section. The maximum displacement, it will be seen, was 3.3 mm., which occurred about 6½ m. below the crest. The crest displacement at full reservoir was 2 mm. The direct-reading measurement of this displacement was 2.2 mm., but the report credits this reading with a possible variation of ± 0.5 mm. The work as a whole is considered by the geodetic bureau to establish the suitability of the triangulation method for such measurements. As the bolts in the face of the dam and the instrument piers will remain in place, future measurements can be made at any time to give a check on the permanence of position and form of the dam.

A 12.76-In. Rainfall in 4½ Hours at Beaumont, Texas

A RAINFALL of 12.76 in. in 4½ hr. was recorded at Beaumont, Tex., on May 18. Through the courtesy of P. C. Day, meteorologist in charge of the Climatological Division of the Weather Bureau, Washington, D. C., the following details of the precipitation for the 12 hr. that included the period of excessive rainfall already noted are made available.

The total rainfall at Beaumont, Tex., from midnight, May 17-18, to noon, May 18, 1923, as measured by John Bender, river observer, Weather Bureau, was 13.54 in. The rainfall measurements are made at Beaumont in an ordinary 8-in. gage at 7 a. m., daily. The amount measured up to 7 a. m. of May 18 was 0.78 in., falling between the preceding midnight and the hour of observation. It is believed that practically all of this amount was gaged between 6 and 7 a. m.

A special reading of the gage was called for from this office (Houston) and made at 11:30 a. m., showing a catch of 12.76 in. during the preceding 4½ hr., the heaviest of which occurred between 7 a. m. and 9 a. m. It is believed that practically all of the amount measured on the 18th, 13.54 in., occurred between 6 a. m. and 11:30 a. m., and most of it between 6:30 a. m. and 9 a. m.

The first estimates of damage done by the excessive rainfall in the city of Beaumont were placed at \$100,000. "Downtown streets were flooded, trees were struck by lightning, an oil tank caught fire, and the city government suffered serious losses as a result of the Beaumont downpour. . . . Water was more than a foot deep in Pearl St. stores, and business was badly handicapped. The rain began falling (heavily) about 6 o'clock and continued in a terrific downpour until shortly before noon. Automobiles were stranded on many of the downtown streets. Hail accompanied the storm. . . ."

Considerable wood-block street paving was floated off during the storm and the storm sewers were inadequate to carry off the water. No lives were lost and the damage seems to have been extremely light in view of the phenomenal rainfall in so brief a time. The excessive rainfall was confined to a small area, with Beaumont as its center, near the mouth of the Neches River. This fact prevented any appreciable rise in the Neches, the stage on the gage being 3.8 ft. at Beaumont on the 17th and reaching a crest of only 4.8 ft. on the 20th.

on a line tangent to the curve of the dam at this point, a method applicable only to readings at crest.

The dam under test is a stone masonry structure of pure arch type located in the valley of the Reuss at Pfaffensprung. It is 70 ft. high and in its main portion 100 ft. in span, with radius of curvature about the same. For the deformation measurements, six bolts were set in the downstream face of the dam about on the line of the crown of the arch, one at the crest, one at base, and four at intermediate levels. Instrument piers were erected on either bank, on rock, close to the abutments of the dam, and a third pier was provided on one bank 40 or 50 ft. upstream of the abutment, to give a sighting line nearly tangent to the curve of the dam at its crown; the latter pier was used for direct reading on a scale attached to the dam crest, while the two other piers, from which the bolts in the face of the dam were visible, were used for the measurements by triangulation. The measurements were carried out at five different water stages, ranging from half the height of the dam to full height. Atmospheric conditions were favorable (sky overcast) and the small size of the reservoir permitted the entire series of measurements

Railway Trestle in Hawaii Fails

BY B. F. RUSH

Inspector of Construction,
Board of Harbor Commissioners, Hawaii

IN MARCH of this year ten bents of a trestle of the Hawaii Consolidated Ry. at Hilo, Hawaii, one by one upset and disappeared into the Wailuku River, each bent falling against and upsetting the adjoining one. The trestle was constructed in 1910. The bents consisted of two cylindrical reinforced-concrete posts 3 ft. in diameter, and a reinforced-concrete cap. In all there were 23 separate bents at 16 ft. centers. Each bent was a unit within itself, no cross bracing to adjacent

FIG. 1—CONDITION OF BRIDGE JUST AFTER COLLAPSE

bents having been provided. The total length of the bridge is 352 ft.

The type of construction is well illustrated in Fig. 2. On each cap was bolted a 12x12-in. timber. Resting on these were six 6x12-in. deck stringers, three under each side of the track.

The posts were constructed by sinking wooden forms to bedrock, excavating the interior, placing steel dowels in the solid rock and then filling the casing with reinforced concrete. At the time of construction there were from 8 to 10 ft. of sand above the solid rock on which the posts rest. This sand was expected to act in place of cross bracing.

From an examination after the failure it was found that most of this sand had washed away; under the section of the trestle which failed there remained only from 2 to 4 ft.

The first bent to fall was on the Wainaku side of the river which is opposite the piledriver shown in Fig. 2. This pier no doubt had been undermined. When it gave way it fell toward the center of the stream striking the adjacent pier and knocking it over. This continued

FIG. 2—DRIVING PILES FOR THE TEMPORARY BRIDGE

One of the overturned bents is resting against the bent under the leads of the driver. The bracing between the caps was put in after the failure.

until in all ten piers were overturned before a bent was reached which was sufficiently embedded in the sand to withstand the force of the blow from the adjacent falling bent.

The failure emphasized two precautions that might have been taken when the original construction was done. Bracing from bent to bent should have been provided and the posts should have been set into the bedrock instead of on top of it.

It is thought that the recent tidal wave which visited Hawaii a short time before the failure had a great deal to do with washing out the sand from the bed of the river.

High Yield From Small Watershed With Large Water Area

BY FREDERIC I. WINSLOW

Consulting Engineer, Framingham, Mass.

A CONSIDERABLY larger yield than appears to be normal from watersheds in Eastern Massachusetts is found at Framingham, in Farm Pond, which is an adjunct (now practically discarded) of the Metropolitan water-works for Boston and adjacent cities. This

TABLE I—HIGH YIELD FROM FARM POND WATERSHED*
Per Cent of Rainfall Appearing as Yield
From Farm Pond

Year	Published Figures	After Correction†	From Entire Sudbury Watershed
1916	95.9	85.0	47.6
1917	100.2	99.1	38.0
1918	98.5	88.2	38.2
1919	69.4	62.1	45.5
1920	83.8	74.7	53.6
1921	76.3	67.3	39.8
1922	66.7	57.6	45.1

* Area of watershed, including water surface, 0.54 sq. mi.; water surface, 0.25 sq. mi.; storage capacity, 216 mg. † Correction made for amount drawn from Pond.

unusual yield may be due to underground flow from a slightly higher watershed, as explained further on.

Table I compares the Farm Pond yield for the last seven years, expressed in percentages of rainfall, with that of the entire Sudbury watershed, (including Farm Pond). For the last forty-eight years the average yield of the Sudbury has been 46 per cent of the rainfall, compared with which the Farm Pond yield for the past seven years has been from 25 to 115 per cent higher.

TABLE II—YIELD IN SECOND-FOOT PER SQUARE MILE OF FARM POND, SUDBURY, WACHUSETT AND COCHITUATE WATERSHEDS

Year	From Farm Pond Using Annual Reports	Corrected as in Table I	Entire Sudbury Watershed	Wachusett Watershed	Cochituate Watershed	Rainfall by Gauge on Sudbury Watershed
1916	2 775	2 459	1 398	1 880	1 588	2 894
1917	3 253	2 902	1 161	1 290	1 216	3 005
1918	2 886	2 583	1 139	1 395	1 173	2 930
1919	2 341	2 094	1 529	1 945	1 634	3 372
1920	3 105	2 769	1 917	2 521	2 171	3 708
1921	2 474	2 183	1 276	1 690	1 518	3 244
1922*	2 211	1 908	1 516	2 045	1 701	3 312

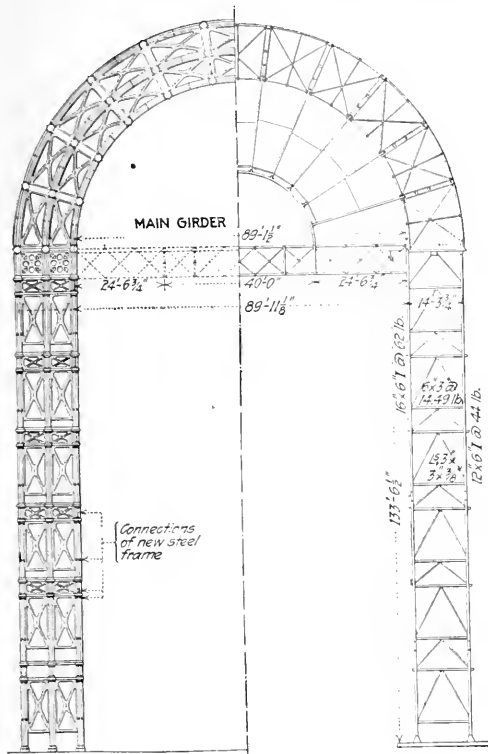

* The figures for 1922 are subject to possible slight correction after being issued in final form.

Table II compares the yield of Farm Pond in second-foot per square mile with that of the Sudbury, Wachusett and Cochituate watersheds.

Observations on the southerly side of Farm Pond show very little water when excavations are made; but on the north side, about 1,650 ft. away, is a pond—Larned's Pond—covering about 42 acres of possibly 100-mg. capacity. This pond is about 7.85 ft. above Farm Pond, and has no visible outlet; but as the soil between the two ponds is largely gravel it may be that enough water passes through to account for the high yield on a different watershed from the last pond.

Old Cast-Iron Frame of Crystal Palace Strengthened by Steel Framing

AFTER seventy years, the well-known Crystal Palace in London was recently repaired in interesting manner. The building is a high, arch-roof structure with cast-iron framing, covering nearly 11 acres of ground surface, and has its entire exterior glazed. It is 384 ft. wide in its main portion and 1,392 ft. long with a clear height above ground of about 192 ft.; the height of the frame above footings is about 195 ft. It was built in 1851 and was expected to last only about 25 years, but is still in excellent condition. The repairs concerned chiefly the east face of the central aisle, which

FRAMING OF EAST FACE OF CRYSTAL PALACE

projects about 25 ft. from the main portion of the building, and they appear chargeable in the main to a weakness in the original construction, consisting of the use of timber plates between the cast-iron segments of the arch.

In the sketch herewith the cast-iron frame of the east face is shown at the left. Each of the two towers consists of three cast-iron posts, which are connected by horizontal girders and diagonal members, also of cast iron. On these towers is seated the arch, whose three ribs continue the lines of the posts of the towers. In the arch, however, radial members connected to a small central half ring (not shown) are inserted, and these radials are 5 x 10-in. timbers which pass between the contact faces of the successive segments and are subject to full arch pressure. Cast fascia members cover the

outside of these members. The material of the radials is untreated soft wood, and decay has been extensive in the course of years, especially near the bolt holes. The result was serious settlement and distortion of the frame, many members being as much as 3 to 7 in. out of true. The method of repair was to erect an independent steel structure back of the cast-iron frame, and bolt all members of the cast-iron frame to the steel frame. The steel frame is shown at the right; its connections to the old frame are partly by direct bolting and partly by brackets carrying steel girders bolted to the cast-iron columns. The main verticals of the steel frame are I-beams, the outer one being 12 x 6 in. and the inner one 16 x 6 in.; they are connected by struts of 6 x 3-in. channels and diagonals of 3 x 3 x 1/2-in. angles. The old frame being not vertical and out of true, the connections between it and the new frame had to be such as to suit the varying horizontal distance between them, for which reason bracket connections were largely used. The work was planned by W. Wright, engineer for the Crystal Palace.

Concrete Road Maintenance Costs in Ohio, 1917-1922

BY E. C. BLOSSER

State Highway Engineer, Columbus, Ohio

OCCURRENCES recently demanded that we make a determination of the relative maintenance costs of plain and reinforced concrete pavements in Ohio, and a careful analysis was made from the maintenance records for the years 1917 to 1922 inclusive. The results are given in the accompanying table.

The widths and depths of the pavements are variable in both cases, the depths ranging from 6 to 9 in. and the costs are for surface only. The reinforced-concrete pavements include those with only circumferential reinforcement and light mesh reinforcement. The average cost of the reinforcement probably did not exceed \$0.12 per square yard.

Using the average costs per square yard, the maintenance cost per mile per year for a plain concrete road

MAINTENANCE COSTS OF PLAIN AND REINFORCED-CONCRETE PAVEMENTS

Year	Sq Yd. Completed	Accumulated Yardage	Total Maintenance Cost	Maintenance Cost per Sq Yd.
1917	2,556,005*	2,556,005	\$23,317	\$0.00990
1918	175,303	2,731,308	29,477	0.01079
1919	321,299	3,052,607	34,892	0.01143
1920	677,758	3,730,365	85,214	0.02284
1921	516,091	4,246,456	145,990	0.03431
1922	520,910	4,767,366	106,986	0.02244
Average.....				\$0.0223
Reinforced Concrete				
1917	628,067*	628,067	\$1,208	0.00192
1918	103,686	731,753	1,793	0.00245
1919	374,817	1,111,570	2,785	0.00250
1920	563,252	1,674,822	7,960	0.00475
1921	315,507	1,990,329	10,610	0.00533
1922	930,673	2,921,002	14,209	0.00487
Average.....				\$0.0043

* These figures include all pavement built prior to 1918.

16 ft. wide is \$209.33 and for a reinforced-concrete road 16 ft. wide is \$40.36. The difference is \$168.97, which capitalized at 5 1/2 per cent equals \$3,072. Considering maintenance costs alone, we are in general justified in expanding this amount for reinforcement. The advantage as to life of pavement probably favors reinforced concrete over plain concrete in the ratio of at least 5 to 4, i.e., if the average life of plain concrete is 20 years, for reinforced concrete it will be at least 25 years.

Underpinning a Church Foundation With Slab Footings

Soil Loading Reduced From 5 to $3\frac{1}{2}$ Tons Per
Square Foot by Spread Footings—Temp-
orary Support by Pretest Piles

BY LAZARUS WHITE

Spencer, White & Prentis, Engineers and Contractors, New York

IN ORDER to reduce the soil loading which would be imposed by the completed structure, a church in course of construction in Brooklyn has just been underpinned with spread footings of increased area. The operation was carried out by undermining the old footings, supporting the structure on "pretest piles" and temporary supports, and constructing the new reinforced-concrete footing slabs in the excavation. The work was rendered difficult and delicate by the fact that services in the church continued throughout the work.

Existing Conditions—The foundations and superstructure to the level of the main floor of the Church

ORIGINAL AND UNDERPINNED FOUNDATIONS OF CHURCH

of Our Lady of Perpetual Help were originally built in 1907 and 1908; a temporary roof was installed and services were conducted in the roomy basement. The structure is spacious, its extreme length being about 250 ft. and its breadth at the altar about 180 ft.

The original foundations were of the spread-footing type, and had been designed for an ultimate load of about 5 tons per square foot on the soil. When building operations were about to be resumed in 1922, the Bureau of Buildings of the borough of Brooklyn, after a reconsideration of the building plans and designs, ruled that the former allowable loading was too high and reduced the loading to $3\frac{1}{2}$ tons per square foot. This placed a very serious problem before the architect, particularly at the tower foundations, whose estimated loads were over 3,000 tons for each tower. It was necessary almost to double the bearing area of each foundation.

The architect, F. Joseph Untersee, of Boston, with J. R. Worcester as consulting engineer, solved the problem of design by providing new and larger reinforced-concrete footings below the old footings, the reinforcement being so placed as to allow the placing of the large tower foundations in sections. To carry out this design it was necessary to underpin the old structure and transfer its load to the new footings. The construction was undertaken by Spencer, White & Prentis, Inc., of New York.

Underpinning Operations—Beginning with the tower foundations, the contractor took up the old floor and excavated to the bottom of the footings at one side of the church entrance, leaving the entrance clear. Excavation was then carried forward under the old foundations, the corners being first undermined and diagonal reinforced-concrete blocks placed under them for preliminary support. Then the entire area beneath the old footings was excavated, by tunneling methods, and pretest cylinders were driven in the soil below as temporary supports for the tower foundation. These cylinders were 14-in. steel pipes filled with concrete, each loaded by a hydraulic jack to 60 tons and then wedged up against the old footing by short lengths of I-beam set vertically on the cylinder as a strut, with steel wedges driven between the I-beams and the bottom of the footing.

With the tower foundation so prepared, a block of reinforced concrete 34 ft. square and 3 ft. thick was poured under the old footing. This operation was difficult chiefly because it had to be carried out in a very cramped space, and necessarily in one run to secure full benefit of the reinforcing. It was carried out in about 12 hr. time for each tower, with the use of an electrically driven mixer set up in the tower. Material was conveyed to the mixer from the sidewalk by wheelbarrows. The new concrete was carried up to within a few inches of the bottom of the old footing, and no attempt was made to obtain a tight contact in the first operation. A liberal number of 3-in. grout pipes were placed around the perimeter of the old footing, some of them being driven from the adjoining yard. Around the inside of the old footing, a sand dam a few inches high was built on the top of the new concrete, to hold the grout and permit its flow and spread from the grout pipes to be checked up. The grout was mixed in a large mortar box and run directly through the pipe. By this method perfect contact was secured between the old and the new concrete.

The small interior footings, each about 10 x 10 ft., were placed by similar methods, the work being carried on from an adjoining pipe tunnel under the church floor. Each of the old footings was supported on four pretest piles, the new concrete footing was then placed, and the contact grouted through holes drilled in the floor. Very little disturbance of the church floor was required in the entire work.

The contract was carried out in a few weeks, with little interference with the services in the church, and was wholly successful in its structural results. The success of the work was due, in the writer's opinion, largely to the skill of the men engaged upon it and to the combination of tunneling and underpinning methods in the operation.

New York State Aid to Health Laboratories

State aid to enable city and county health laboratories to provide laboratory service for local medical practitioners and for health officers is authorized by an act of the New York legislature of 1923 which carries an appropriation of \$25,000 for the expenses of the State Department of Health to put the act in effect. The department may grant \$2,500 towards the initial cost of installing and equipping such laboratories and may pay one-half the maintenance cost but not to exceed \$7,500 a year for any one laboratory.

Building a 50-Kilometer Railroad Through Tropical Swamps

Log Cribs Substituted for Dirt Fills—Rude Barge Transports Materials—Pony Bents on Falsework Support Steel Span

By FRANCIS R. MOLTIER

Former Office Engineer, D. E. Wright Construction and Engineering Co., Inc., Panama

THE ECONOMIC desirability of putting a 50-km. stretch of railway in Honduras, C. A., into operating condition at the earliest date possible urged the employment of certain unusual devices to expedite construction. The use of these devices, while not generally commendable from the point of view of engineering practice, was justified by the existing conditions which made the expense of the construction a secondary consideration, and is explained here with that understanding.

The urgency of this work was complicated by the fact that the weather was most unseasonable for such extraordinary effort, heavy and continuous rains causing floods over much of the low territory in which the line was located. It was determined, therefore, to form log cribs or grillages, through the shallow fills from three to ten feet in height, for the purpose of carrying the ties and rails until the dry season might make the manipulation of the adjacent material more convenient. It was planned to make much of the actual fill by train, thus reducing the cost of handling the earth over cost of placing it by hand, beside making execution possible under less urgent conditions. The absorption of the logs due to decomposition obviously indicated that bringing the line to grade with earth would be a question of several years.

The first course was laid so as to provide longitudinal members, parallel to the rails, in the top course of the crib, alternating longitudinal and transverse systems between them. The material was hauled into place with oxen, owing to the great capacity of these animals for work in soft ground. The ties were shimmed to grade as much as possible, but the use of thin shims was generally avoided. In dry weather this flooded territory bakes as dry and hard as pottery, making the timber fills look strangely out of place.

The route of this line crossed a river with a 200-ft. through-riveted span about three kilometers from a switch to the main line. This stream cut off the laying of track during the time required for the erection of a temporary trestle, although grading was complete for some distance on the far side of the stream.

For the purpose of laying steel on the distant graded section, which not only assured the use of that portion as soon as the trestle might be completed, but also furthered the progress of more remote grading, a barge or ferry was rigged up to convey ties, rails and accessories to the other side.

The barge was swung from two pulleys traveling on a steel cable spliced around stout trees on the opposite banks. The lines to the pulleys were adjusted at different lengths, so that the upstream side of the barge was presented to the current at an angle that furnished some assistance from the flow in crossing with the barge loaded. A manila rope swung from the same trees, and connected to the barge with a hand-line running on the rope by means of an eye, furnished the means to haul the barge back when unloaded.

One or two fills between 500 and 1,000 ft. long which delayed the laying of rail on completed grading beyond them required the use of a detour to get material to the completed dump ahead.

As soon as steel was laid to the end of the completed grade, 20-lb. rail was laid from this point down into the gully where grading was incomplete, but outside the toe of the proposed fill. This light rail was continued up to the completed work ahead, where ties, rail and accessories were received from hand cars loaded alongside the regular flat-cars that were run to the end of rail and the beginning of the detour. Oxen and men hauled the hand cars over the light rail.

In the figure are shown pony bents built on top of regular falsework for a through-riveted steel truss bridge, to facilitate the removal of the falsework after the truss was erected. The falsework was of four-pile double-braced construction cut off to place the main

DETAIL OF PONY BENTS

caps 5 ft. under the bottom chord of the bridge. Through pile pony bents were built of 12 x 12-in. material, also double braced, to 6 in. below the level of the bottom chord, which proved sufficiently sturdy to carry the steel.

State Bureau of Housing and Regional Planning for New York

A STATE Bureau of Housing and Regional Planning within the Department of Architecture was created by the legislature of 1923 and \$10,000 appropriated for its expenses. The bureau will be in charge of a commission of eight members, consisting of the state architect, the state highway commissioner (now a bureau head in the Department of Public Works) and the state industrial commissioner, ex-officio, and five "lay members" appointed by the state architect. All the members serve without salary but are to receive traveling expenses. Besides being required to make a special report on the present housing shortage and a yearly general report the duties of the new bureau are:

1. Study housing needs and conditions in the State and prepare plans adapted to meet such needs and conditions.
2. Collect and distribute information relating to housing and community planning and study means of lowering rent on dwellings by securing economy in the construction and the arrangement of the buildings.
3. Assist in the preparation of legislation and regulations in relation to housing, zoning and planning throughout the State.
4. Co-operate with local housing boards or similar bodies in cities and localities and with State and Federal authorities.

Hints That Cut Cost and Time

For the Contractor and the Engineer

Small Motor-Driven Foundation Hoists

INDIVIDUAL electric hoists with 2-hp. motors are being used in sinking the 160 foundation wells for the Illinois Merchants' Bank Building, Chicago, instead of the more usual arrangement of having the hoists for a row of wells operated by an endless running rope driven by an engine or motor. This new arrangement is shown in the accompanying view. At each well there is the usual tripod carrying a sheave over the well and having a canvas cover for weather protection. Ord-

cables across the site and are both convenient and economical where wells cannot be operated in rows but must be handled singly.

These new electric hoists, which have been used also in trench excavation, are built by Louis Falzer & Co., Chicago. At the Illinois Merchants' Bank Building, eighteen hoists are in use for sinking the 160 wells by the Henry Ericsson Co., Chicago, contractors for the building.

Ice as a Protection Against Ice in Exposed Penstocks

BY J. LEROY UNDERHILL

Inspector, Vermont Department of Highways

AFTER several winters in which the half mile of 6-ft. penstock at power house No. 4 of the Montpelier & Barre Light & Power Co. had been a continued source of trouble and expense due to ice forming on the inside, Mr. Lawrence, the chief engineer of the company, resorted to an unusual method of protecting the penstock against further frost action. On the first 1,500 ft. below the dam he had $\frac{3}{4}$ -in. holes drilled in the top of the penstock at 12 ft. centers. For the remainder of the distance the same spacing was used, but due to increased head, the diameter of the holes was reduced to $\frac{1}{2}$ in.

The accompanying photograph shows the results that were obtained, and after having been used for four winters, the method is endorsed by Mr. Lawrence as being a very satisfactory means of preventing interior ice formation. It is usually necessary to keep the ice chopped down until sufficient water has escaped to form the required thickness of covering after which the jets may be allowed to flow until frozen.

Contrary to belief, it is not necessary to plug the holes in the Spring. Owing to their small diameter, they are effectively closed by the large amount of sus-

SHAFT HOIST WITH 2-HP. MOTOR

narly, a short shaft mounted on one post of the tripod carries a niggerhead or drum at the inner or well side and has at the outer end a grooved sheave around which the driving cable is looped.

With the new equipment, the drum, shaft, motor and transmission or reducing gear form a self-contained unit mounted in tandem on a bed plate, one end of which is supported by a steel leg while the other end rests on a timber placed across two posts of the tripod. In the view the well is partly covered with planks. From the drum the rope passes up over the head sheave and down to the bucket. The drum runs continually and the rope makes two or three turns around it, the hoist man drawing the rope tightly upon it to get the friction necessary for hoisting, or letting the rope run loose for the bucket to overhaul in lowering.

Flexibility and convenience of operation are among the advantages claimed for the individual motor-driven hoist system. Each well is independent of the others and as soon as it is completed the hoist can be shifted to another site. But with the cable system the rig for a set of wells must remain in place until the last one is completed, although it may be operating only one or two of the wells; and time is also consumed in making the set-up for another row of wells. Furthermore, the individual hoists avoid the trouble of long running

ICE JACKET AROUND THE EXPOSED PENSTOCK

pended matter carried in the water at that period of the year. They can be easily cleared with a sharp-pointed tool when it is desired to prepare the penstock for Winter again.

Bucket Elevator Useful in Excavating Basement

THE CONSTRUCTION program on an office building in Fresno, Calif., being built for the San Joaquin Light & Power Corp., was such that it was necessary to remove several hundred cubic yards of earth after the foundation walls and part of the superstructure had been built. An old bucket elevator of suitable size was available and the contractor set this up in one corner of the basement and operated it at low cost with a 4-hp. gasoline engine.

The elevator was set so that with its lower end below the basement floor level its upper end would deliver through a short chute directly into trucks standing in an alley. A belt drive was used between engine and elevator and the use of a 30-in. pulley at the upper or elevator end of the belt gave the desired speed. Alongside the driving pulley was an idler pulley onto which the belt could be slipped by pushing a lever. Thus the gasoline engine was allowed to run continuously but by shifting to and from the idler pulley the bucket elevator proper was operated only when a truck was in position to receive the material. This did away with the necessity of bunkers. The shaft driven by the belt carried a smooth-face double-flanged wheel over which the links of the bucket elevator passed, the friction being sufficient to drive the elevator without the use of sprocket teeth.

No bin or other receptacle was provided at the lower end of the elevator, the material being merely piled up by shoveling or dumping from wheelbarrows. A shovel man was kept in attendance at the lower end when the elevator was working to shovel spillage from the buckets back onto the feed pile. As many as 12 men were

BUCKET ELEVATOR FOR LOADING FROM BASEMENT

required in the basement to keep the elevator busy when the material had to be moved by wheelbarrows the maximum distance of 60 to 75 ft.

One man was required at the top to start and stop the elevator and generally superintend its operation and the loading of trucks. Trucks handling 5 cu.yd. were loaded in about twelve minutes.

The contract is being carried out by the R. F. Felchin Co. of Fresno for whom E. M. Lewis is superintendent of construction.

Street Sprinkler Used in Curing Concrete Pavement

By J. G. BRAGG

Senior Testing Engineer, New Jersey Highway Department, Trenton, N. J.

THE New Jersey state highway specifications require that concrete pavements be covered with salt hay or straw as soon as possible after placing the concrete, and this covering kept damp for a period of at least ten days. The usual procedure is to take the water from a pipe line supplying the mixer, hose connections having been provided at frequent intervals for

SPRINKLER WITH SPECIALLY MADE DISTRIBUTOR

that purpose. In cases where the road is constructed full width in one operation, from one-half to one mile of road is being cured at all times. If the covering is kept sufficiently moist, this is by no means a small undertaking, but it becomes still more difficult when the pavement is constructed one-half width because of the greater length to be cured.

The accompanying photograph shows portions of half-width construction being efficiently sprinkled with a horse-drawn street sprinkler, equipped with a special distributor consisting of a length of galvanized leader pipe in which holes have been bored about 5 in. apart. The distributor is hung on a pivot so that it may be swung to either side of the sprinkler.

The road under construction is known as Section 8 of State Highway Route 9, between Somerville and North Branch, N. J., and was built by Ralph Sangiovanni, of Newark, N. J.

Excavation Costs by Draglines

AVERAGE unit costs of comparable dragline excavation of drains for the 1922 season on some of the U. S. Reclamation Service projects are given in the following table. Costs are for machine operation only with no overhead:

Project	Cu.Yd.	Unit Cost	Dragline Machines Used
Shoshone	836,800	\$0.110	3 Bucyrus 9½ elec.; 1 Bucyrus 9½ gas; 1 Bucyrus 14 gas; 2 Pawling & Harnischfeger 206 gas
No. Platte	522,085	.121	2 Monaghan 1T gas; 1 Bucyrus 9½ elec.; 1 Bucyrus 14 gas; 1 Pawling & Harnischfeger 206 gas
Newlands	1,706,816	.091	2 Bucyrus 14 gas; 1 Pawling & Harnischfeger 208 gas; 1 Austin 4 gas; 3 Monaghan 1T gas
Rio Grande	1,770,605	.072	5 Bucyrus 9½ gas; 1 Monaghan 2T gas; 3 Pawling & Harnischfeger 206 gas; 1 Bucyrus 303 gas

In the table below is shown the average cost of canal excavation by draglines this season. As for the drains these costs are for machine operation only. Drilling and blasting and engineering and overhead are not included in costs.

Project	Cu.Yd.	Unit Cost	Dragline Machines Used
Klamath	442,737	\$0.120	1 Monighan 1T gas; 1 Bucyrus 30 gas; 1 Bucyrus 14 gas; 1 Pawling & Harnischfeger 206 gas.
N. Platte	1,149,782	.107	1 Monighan 1T gas; 1 Bucyrus 14 gas; 2 Bucyrus 91 elec.

Metal Clamp for Concrete Column Forms Saves Cost and Time

CONCRETE column forms on the sixteen-story Matson Building, just completed in San Francisco, were held in place by a new type of clamp which, according

CLOSE VIEW OF CLAMP IN POSITION ON FORM

to the Lindgren Co., general contractors, saved \$1,500 on this job over the cost of accomplishing the same purpose with the ordinary wooden clamps. A further economy resulted from being able to fill the column forms to the top in one continuous operation as fast as the concrete could be dumped from the buggies. The surrounding slab was poured as soon as the column form was full, the runway for the buggies being moved back as the pour advanced and each succeeding column being filled as it was reached. This reduced the number of runways required to make the pour and also the labor of shifting them around. Since its success on this job the device has been patented as the "Wedge Notch Form Clamp."

As used on the Matson Building the clamps consisted of two pairs of intersecting arms, 3 ft. long, and two wedges. Each pair of arms consisted of one double bar (two 2½-in. pieces) and one single bar (one 2½-in. piece). The single bar was held between the double bars by a ½-in. loose rivet which was secured with a cotter pin. The double bar was held together at the other end and at the center by countersunk rivets with ½-in. washers as spacers between the bars.

The ends of the bars were notched, the notches being on the outside of the arms and set at an angle of 45 deg. with the longitudinal axis. The wedges were 8 in. long, ½ in. thick and tapered from a 2-in. width at the top to a ½-in. bottom width. The complete clamp weighed 37 lb., or about the same as the wooden clamp which it replaced. In the size used on this building the clamps were adjustable to any rectangular column from 6 in. to 30 in. square. This range was made possible by a hole in each arm half way from hinge to

From Job and Office

Hints that Cut Cost and Time

notch into which the loose rivet hinge could be transferred when clamping smaller sized forms. The loose rivet was used in place of a bolt to avoid delay in making shifts that might otherwise be due to rust or concrete in the bolt threads.

The column forms were made on a bench, placed in the usual way and held temporarily by nailing the edges of the panels together at bottom, center and top. The first steel clamp was then placed 9 in. above the floor and each succeeding clamp 18 in. above the one last placed. In setting the clamps the single bar in each pair of arms was slid through the double bar in the opposing pair until all four arms rested against the form. The wedges were then inserted so as to engage opposed notches and driven home with a hammer. It was found that the wedges exerted sufficient pressure to draw the form boards tightly together and prevent any leakage of water and cement.

As the forms were set higher up the column the men soon found that they could climb up on the clamps, hooking one knee over the projecting arm of the top clamp and resting the other foot on the next clamp below. In this way, and taking the average for the job, the seven clamps on a column were placed by two men in twelve minutes and one man stripped the seven clamps and piled them at the base of the column in four minutes. These figures, which give an average for clamping and stripping of one man's time for four minutes on each clamp, were used in estimating the comparative saving of the metal clamps over wooden clamps. The cost of using wooden clamps was estimated on the basis of lumber costing \$35 per M. or 35 cents per clamp, framing 40 cents and removal 5 cents, or a total of 80 cents per wooden clamp.

The first story columns on the street fronts of this building are T-shaped. To use the steel clamps on these columns 2-in. filler blocks were cut to fit between the stem of the T and the clamps.

Prize for Street-Railway Crossing Design

One of the members of the Contractors' Association of Philadelphia has offered a \$50 prize for an expression of the best idea or experience in connection with paving a street intersection containing a railway crossing. The contest is open to anyone connected with public construction work.

New Method of Placing Column Shoes for Steel Frame Buildings

A CONVENIENT method of setting column shoes and grillage on the foundation piers of large buildings is being employed in the construction of the new Union Station at Chicago. It permits of more rapid erection and insures stable support for shoe and column.

In common practice, after the head of the pier has been cleaned of laitance and foreign material, the shoe is placed on brick or concrete blocking on top of the

SCREW SUPPORTS FOR COLUMN SHOES

pier and, after it is adjusted to level, grout is poured in through holes in the base to fill the 3- to 6-in. space between the shoe and the pier. This grout is usually required to be left for 70 to 90 hours before any load is placed on the shoe. When a girder is to be fitted against the web of the column, it is customary for the erector to push the column laterally so that the girder will clear the flanges. This movement of the column frequently results in a tipping of the shoe and crushing of the grout under its edges, especially as the grouting is often more or less incomplete or defective. Tilting of the shoe in this way may result in considerable expense and delay by making it necessary to remove the column, readjust the shoe and then start the steelwork again.

The new method of carrying the shoe consists of providing an adjustable support which will hold the shoe in place until the grouting has been completed, and which will take care of erection stresses until the grout has hardened sufficiently to take the required stress. Four taper holes are cored in the shoe base, and threaded taper bushings of soft steel are set in them, as shown by the sketch. Four 1-in. steel rods 10 ft. long, threaded for their entire length, are used for raising or lowering the shoe.

When the shoe is to be placed, the four rods are screwed into the threaded bushings, so as to project 12 or 14 in. below the base. A nut and washer on top of the base are screwed up when the shoe has been adjusted so as to prevent the shoe from tipping. Two square nuts are locked on the upper part of each rod, above the shoe. The shoe is brought to exact level by gripping each threaded bar with a wrench applied to the locked nuts, thus turning the bars like screw jacks until the shoe is raised or lowered to proper level. Wedges driven between the shoe and the wood lagging of the pier prevent lateral displacement of the shoe. Then 1:1 grout is pumped in to fill the space under the shoe. To bond this grout cap to the pier, two hook-end bars have their vertical ends set in the concrete at the time the pier is being completed.

When the grouting is completed, the projecting ends of the threaded rods are broken off above the nuts and washers with a cold chisel, and are used in another shoe.

The usual cost of setting one shoe by the old method ranges between \$50 and \$300, and sometimes reaches \$400 with a large shoe or grillage lowered to a considerable depth in the casing or well above the top of the pier. With the rod method, the labor cost of setting a shoe averages about \$12, and the total cost \$22.

This new method of securing column shoes to concrete piers for support of steel structural work was invented by G. W. Allen, superintendent of construction for Graham, Anderson, Probst & White, of Chicago, who are the architects for the Union Station.

Double Layer Reinforcement for Roads

By R. JOHNSTONE-TAYLOR
Shrewsbury, England

WITH the idea of developing the most effective type of reinforcement for reinforced-concrete roads a number of British engineers have devised a system of double layer reinforcing, the theories upon which it is used being explained below.

The nature of the effective loading is always indefinite and there cannot be exact knowledge regarding the action of the ground in supporting the slab. The advantage generally assigned to a double layer fabric is that it will take up tensile stress occurring along the upper part of the slab under certain conditions and will also provide for shear stress due to heavily-loaded axles supporting machines traveling at high speed.

The type of double layer reinforcement used consists of a bottom layer, a top layer, and a connecting fabric. The first and second consist of hard drawn steel mesh, the transverse members being electrically welded to the longitudinal members. The assembly on the site

DOUBLE LAYER ROAD REINFORCING

is perfectly simple and the method of doing the work is evident from the illustration.

Simulating Summer Conditions for Mid-Winter Construction

TO CARRY ON a large building operation in the midst of Adirondack winter conditions without the loss of a single day's work due to the cold, or storm, was the unique record made at Lake Placid last winter. The operation included the construction of the first three units of the new Lake Placid club house, a reinforced-concrete structure, faced with a local rubble stone up to the second story level and with rough texture chocolate-brown brick above. The three units are: Unit A, 44x105 ft., five and six stories and basement; Unit B, 35x38 ft., four stories and basement; and Unit C, 17x32 ft., five stories and basement. The frame is of reinforced concrete in bays 18x21 ft. with a 6-ft. corridor between them, running lengthwise of buildings A and B. The floors are structural slabs, 2 in. thick, reinforced with mesh for temperature stresses only, carried on reinforced-concrete ribs 25 in. on centers. Over this slab is placed 2 in. of cinder concrete with

FIG. 1—INTERIOR OF THE ENCLOSURE SHOWING THE METHOD OF FRAMING AND SUPPORTING FORMS

wooden sleepers on 12-in. centers laid flush with the surface. The maple floor is nailed direct to the sleepers without the use of underflooring. The corridors are floored with cork tile laid on cinder concrete with a troweled cement finish. Partitions, except at stair and elevator shafts, are of gypsum.

In order to carry out the work during the winter a wooden inclosure was built around the space to be occupied by the completed building and made larger than the building to allow for a working space of about 5 ft. between the finished walls of the new building and the sides of the inclosure. The roof of the inclosure was supported on wooden bents to the full height of the temporary structure. These bents were placed 10 ft. on centers and they were made up of 3x4 verticals, braced transversely and longitudinally.

The exterior walls were of 2x6 material, 30 in. on centers, sheathed on the outside with 1-in. matched boards, and faced on the inside with tar paper.

Fig. 1 well illustrates the type of framing and the method of supporting the forms for concrete. All forms were of wood. The posts were built into the floor slabs and later cut off flush. 150,000 ft. b.m. of lumber were required for the inclosure.

After the inclosure was roofed over, it was heated by a B. F. Sturtevant Vento system, with a capacity of

From Job and Office

Hints that Cut Cost and Time

FIG. 2—THE ENCLOSURE IN MID-WINTER

15,000 cu.ft. per min. at a temperature of 150 degrees. Steam was supplied from the boilers serving the present buildings of the Lake Placid Club. The coal consumption averaged $3\frac{1}{2}$ tons a day. The heated air was distributed throughout the inclosure in wooden ducts. Artificial lighting was necessary inside the building after the outside walls and interior partitions were up, only a few small windows having been placed in the sides of the inclosure.

Excavation for the foundations was begun on Nov. 23, 1922, by the owners of the property, the Lake Placid Club Co. Even at that early date the ground was frozen enough to require blasting. The footings were started on Nov. 29, and completed on Dec. 7. They were carried to a depth of $5\frac{1}{2}$ ft. below the finished external grade. Their depth was dictated by frost penetration rather than by the class of material on which they were built. Measurements of the depth of frost penetration this spring showed 62 in.

The work on the foundation walls and the first floor was carried on before the inclosure was completed, all exposed work being protected by canvas covers and heated with coke salamanders. The inclosure was completed to the fifth floor level and roofed over on Jan. 11. The heat was then turned into it and thereafter the men could work inside without heavy coats and gloves, the temperature averaging above 55 degrees, except on some

FIG. 3—REMOVING THE ENCLOSURE IN THE SPRING

From Job and Office

For Contractor and Engineer

extremely cold days. Only once did a thermometer register down to freezing inside the inclosure and then only along the ground below the level of the heating ducts. At the time the outside temperature was 32 degrees below zero. Specimen temperatures on days of low temperature were as follows: Outside, 36 below zero, inside 40 to 58 above; outside 24 below, inside 42 to 46 above.

As much of the building material as could be obtained in the early winter was brought to the site while the roads were good and was stored outside the inclosure, under canvas covers. Some of the reinforcing steel was later stored in one of the clear spaces within the inclosure. Materials for the concrete were heated with steam, since it was necessary to store these materials outside of the inclosure.

When the building was started a progress schedule was prepared, and except for the first and second floors, was followed so closely that the high roof was completed on the schedule date, March 1. The progress was as follows:

1st floor concreting completed A—Jan. 12; B—Jan. 18; C—Jan. 23.
2nd floor concreting completed A—Jan. 27; B—Jan. 28; C—Jan. 29.
3rd floor concreting completed A—Feb. 2; B—Feb. 3; C—Feb. 5.
4th floor concreting completed A—Feb. 8; B—Feb. 9; C—Feb. 10.
5th floor concreting completed A—Feb. 11; B—Feb. 15; C—Feb. 16.
6th floor concreting completed A—March 1.

The plastering was all done before the inclosure was removed, flood lighting being used to provide proper illumination. The building was substantially completed on May 15, and the inclosure was completely dismantled by April 28.

This work was done by the Turner Construction Co., New York. The architect was William G. Distin, Saranac Lake, N. Y. Information for this article was furnished by H. H. Alger.

"Duckboards" Handy for Building Concrete Buggy Runways

WHERE concrete buggies have to be wheeled over runways or ramps supported on trestles, the R. F. Felchin Co. of Fresno builds up the runways quickly and at low cost by the use of sections called "duckboards." These are 4x14 ft. in size and consist of 1x6-in. boards cut in 4-ft. lengths and nailed as a flooring onto three 14-ft. 3x4's that serve as joists. One of the 3x4's is placed in the center section and the others are placed 1½ in. inside each edge of the 4-ft. flooring, thus the sections are light and easy to handle, and, since they can be quickly made from old ferm lumber, do not cost much.

The duckboards are used repeatedly and as they pile up in small space can be readily stored or taken from job to job. When supporting these sections on trestles they are held in place by short lengths of scantling nailed to the support and to the outer joists. When this is done the result is much stronger and safer construction than loose planks and can be put in place almost as quickly. Outer joists are not set more than 1½ in. from the ends of the board because a greater overhang is likely to be broken off under the wheels of the loaded buggies.

Cement Protected From Weather by Tent Placed With Derrick

IN RAISING the height of the Copco Dam, which is near the California-Oregon line, a canvas tent stretched over a light wooden framework was found to be a convenient and economical means of protecting cement from sudden rainstorms or from heavy dew during the night. Cement storage warehouses were permanently roofed over, of course, but the comparatively small quantity of cement kept piled on the platform alongside the concrete mixer could not be kept

LOWERING THE TENT TO THE CEMENT PLATFORM

Tent is lowered by derrick at the end of each night's run over cement remaining on the mixer platform.

under a permanent roof without rehandling because delivery was made from directly above by means of a derrick.

The tent on its wooden frame was therefore built up and set at a convenient spot where the derrick boom could reach it, and at the close of the day's work or whenever operations were stopped on account of rainfall, this tent was picked up bodily by the derrick and lowered into place over the cement that remained on the platform at the mixer. The same tent was used through the two winter seasons over which the work was in progress.

The raising of the Copco Dam was done under the supervision of P. O. Crawford, chief engineer, California Oregon Power Co.

Letters to the Editor

This department aims to be a forum for the discussion of the views of engineers and contractors. The range of interest should be as wide as possible. Contributors are, therefore, asked to make their letters short.

Selling Cement by Sack

Sir—I have observed with interest your reference, under the caption "A Rational Change," to the adoption of the sack unit for selling and invoicing cement, in *Engineering News-Record* of June 21, 1923.

In this connection I may state that this company adopted the sack unit quite a while before either of the companies mentioned, and it may be interesting for you to know that the sack unit is now observed by nearly all of the cement manufacturers in this section including mills in the Rocky Mountain district.

We believed it to be a desirable change, and it is pleasing to note the commendatory attitude of the trade.

L. T. SUNDERLAND,
President, Ash Grove Lime
& Portland Cement Co.
Kansas City, Mo.,
June 28, 1923.

Safe Roadway Widths

Sir—In the letter by L. R. Ash on roadway widths in May 17 issue, p. 894, with reference to Mr. Kipp's article in *Engineering News-Record*, April 19, p. 699, it is evident that the term roadway is confused with that of pavement. I believe it is general practice to consider the width of roadway to include the shoulders on either side of the pavement, or traveled road metal. Of course, with earth roads and, in some cases, gravel surfaces the two terms are identical.

Assuming that Mr. Ash's comments apply to widths of pavements the question arises as to what width is logical to provide for two lines of traffic, or, in other words, for a double track road. The average truck body is not greater than 8 ft. wide and the maximum width over all of a passenger automobile is 5.5 ft. Of course there are trucks operating on our highways with bodies greater than 8 ft. in width, but widths are restricted by statute in most states now, and doubtless will be by all in time. The speed of trucks, especially those loaded to the legal limit, is also limited by state laws. To construct a pavement for the exceptional case of excessive truck body width or for truck speeds exceeding legal limits cannot be justified economically. With trucks, 8 ft. wide, passing on an 18-ft. pavement and with the outside wheels 18 in. from the edges, there is a clearance of 2 ft. between bodies. This clearance is too little for high speed operation or even for comfort, but it indicates that trucks can pass with the wheels remaining well on the pavement. However, the writer believes that the correct criterion for determining the proper width of pavement is obtained when a passenger automobile passes a truck. This case would apply to at least 90 per cent of the highway mileage. By this criterion center clearance on 18-ft. pavement is 3½ ft., which is believed to be ample for high speed traffic. The general practice on all modern road improvements is to widen the pavement on curves, which eliminates that complication. It is not believed that the additional cost of pavement width greater than 18 ft. for a double track road can be justified from an economical standpoint, and there is a practical objection to a width of 20 ft. This objection is based on the observation that a 20-ft. width invites a third line of traffic with the attendant risk of accident because of the small clearances provided. In other words there is danger in increasing the width beyond what is ample for the great preponderance of traffic and still does not encourage the passing of slow-moving by high-speed vehicles, forcing a third traffic lane for which the pavement was not designed.

For two lines of high-speed passenger automobile traffic

and one line of slow-moving truck traffic an analysis similar to this indicates a required pavement width of 27 ft.

With reference to types of construction it is a well known fact that macadam with a bituminous top course breaks off in "scallops" at the edges, thus decreasing the effective width. On the other hand, in the case of rigid pavements the occurrence of dangerous ruts in the shoulder adjacent to the pavement is more frequent and pronounced than in the flexible type and the traffic will consequently not venture so near to the edges of the pavement, the practical effect of which is to decrease the effective width.

Columbus, Ohio,
May 29, 1923.

G. F. SCHLESINGER,
Consulting Engineer.

Interpretation of New York Timber Tests

Sir—Your brief analysis of the timber tests conducted under the auspices of the New York Lumber Trade Association, in the issue of June 21, contains one or two erroneous statements to which I would beg to call your attention. The purpose of these tests was not the comparative study of the two species of wood tested, but an attempt to secure some practical data upon which to base a proposed revision of the New York Building Code. It was the consensus of opinion of those engaged in the lumber industry in this section that the recommendations of the U. S. Forest Products Laboratory were at least not applicable to the character and quality of timber available in the New York market.

The test specimens of both Southern pine and Douglas fir were selected from commercial stocks of local yards, except that during the progress of the tests a shipment of 15 especially selected Douglas fir specimens was received from the West Coast via the Baltimore yards of the Weyerhaeuser company, of which 13 were tested and gave the excellent results noted. These specimens were not included in the original test program nor do they represent a grade available in this market either at the time of tests or at present. The results of the tests on the special timbers were not considered by the New York Lumber Trade Association.

The tests proved that the ordinary run of Southern longleaf yellow pine available in the New York market could safely be used at the working stresses in bending specified by the existing building code (of Mar. 30, 1915), but that the stresses for ordinary run Douglas fir as proposed for amendment of the code of Mar. 1, 1921, through the recommendation of the Board of Standards and Appeals were excessive. The tests also indicated the character and quality of defects that are commonly encountered in both species and gave valuable data as to their influence on the strength of structural size members. It was also clearly demonstrated that to equal the ordinary run Southern longleaf yellow pine, which consisted in large part of S₂ and S₁ specimens under the proposed rules of the U. S. Forest Products Laboratory, it would be necessary to specify the higher S₂ grade of Douglas fir.

The proposed standardization of grades of structural timbers, as contemplated by the recommendations of the U. S. Forest Products Laboratory, loses sight of the desired goal of this process, that is, economical manufacture and use. The rules recommended, besides being too complicated, exacting and impractical in application, do not secure results that warrant the greater expenditure of time and waste of raw material required by them.

The National Lumber Manufacturers' Association has compiled the recommendations of the Southern Pine Association and the West Coast Forest Products Bureau governing standardized grades which have been presented to the timber committees of the several technical societies whose activities involve the study and use of structural timbers. These recommendations provide for three structural grades, standard, select structural and common, and are adaptable to practical methods of manufacture as developed by the lumberman after years of experience with his product.

GEORGE E. STREHAN,
Consulting Engineer,
Southern Pine Association.

New York, June 25.

News of the Week

CURRENT EVENTS IN THE CIVIL ENGINEERING AND CONTRACTING FIELDS

News Brevities

Fire Caused by an Explosion destroyed the municipally-owned garbage-reduction works of New Bedford, Mass., on June 22.

A Net Income of \$20,635,186 for the year 1922 is reported by the New York Central. This amounts to 7.20 per cent on the common stock as compared with 8.93 per cent in 1921, and a deficit in 1920.

The Bill Providing for the construction of branch lines to the Canadian National Railways during a period of three years at a cost of approximately \$28,000,000, which was passed by the House of Commons, was rejected by the Senate on June 29, by a vote of 47 to 10.

Four Hundred Pullman Cars were used for the accommodation of the Shriners at Washington during the recent convention. To keep the storage batteries of these cars charged while they were standing still the Pennsylvania R.R. used 130 lighting plants with a capacity of 1½ kw. and supplying current at 32 volts, mounted on skids and distributed among the cars.

Appointment of "a Professional Engineer of broad experience" as a member of the Milwaukee Sewerage Commission, to fill a vacancy caused by resignation, has been urged upon the mayor by the Engineers Society of Milwaukee. It is pointed out that results previously achieved by the commission when an engineer was a member are recommendation for the appointment of another engineer to that body.

As Soon As the Detailed plans and specifications for the improvement of Montreal Harbor, at an estimated cost of \$10,000,000, have been approved by the Dominion government the work will begin. The program includes the extension of the grain storage and handling capacity at Windmill Point and deepening of the basin there; reconstruction and heightening of wharves; construction of new wharves and railway connections for the grain elevator at Tarte pier now under construction; and extensions of piers in the central harbor.

The Harbor Car Service Bureau, organized for centralizing the handling, tracing and checking of railroad cars on the San Francisco waterfront, is now operating with offices at 110 Market street, San Francisco. It was formed by fourteen of the largest steamship and stevedoring companies. A complete record of movements of all steamer lines will be kept for the benefit of shippers and correct information on car loadings, toll, wharfage, switching, demurrage, etc., supplied. The bureau's services are free of charge to shippers and consignees. Anthony W. Frost is superintendent of the bureau.

President's Coal Commission Reports on the Anthracite Mines

Document Contains 30,000 Words—Strict Regulation Rather Than Government Ownership Recommended—Analysis of Cost

The preliminary report of the United States Coal Commission made public on July 8 is a unanimous report and was signed by the following members of the commission: John Hays Hammond, a mining engineer, chairman; Thomas R. Marshall, former vice-president of the United States; Clark Howell, editor of the *Atlanta Constitution*; George Otis Smith, director of

the Geological Survey; Edward T. Devine, an authority on social relations; and Charles P. Neill, former commissioner of labor.

In the beginning the report points out that the fundamental fact in the anthracite coal problem is that heretofore the limited and exhaustible natural deposits have been in the absolute private possession of their legal owners, to be developed or withheld at will, to be released for such royalties as could be exacted, to be transported and distributed at such rates and in such manner as a doubleheaded railroad and coal combination might find most advantageous, and to be sold at such prices as could be maintained by the restriction of output and the elimination of independent competitors. The commission does not recommend the abolition of existing property rights nor does it recommend government ownership either by purchase at present value or by expropriation. It does, however, hold the view that a limited natural monopoly like anthracite held by a relatively small number of individuals and supplying a necessity for millions of people cannot continue to be treated as if it were not affected by a public interest.

CONSIDERED PUBLIC NECESSITY

Coal is quite as much a public necessity as gas, street railway service, railroads, and like them should be required to report to a public authority and be subject to regulation in the public interest and should have no secrets from the public in regard to mining costs, profits, salaries, wages, or corporate relations. The commission believes that the principal of individual and corporate responsibility should be maintained as most likely to insure economical and efficient management of the industry, and that the public interest may be adequately safeguarded by the creation of a governmental authority with power to require financial and operating reports, to prescribe uniform methods of cost accounting, and to determine the conditions on which coal may be shipped in interstate commerce.

It is recommended that the president of the United States be authorized by act of Congress to declare that a national emergency exists whenever, through failure of operators and miners in the anthracite industry to agree or for any other reason, there is a suspension of mining operations; and to take over the operation of the mines and transportation and distribution of the product with full power to determine wages and price at which coal shall be sold; and subject to court review, the compensation to be paid to land and mine owners.

Am. Soc. C. E. Board of Direction Protests Ousting of Davis

Engineering News-Record Staff Report

Preparation of a strong statement decrying the removal of A. P. Davis from the directorship of the Reclamation Service, and approval of the Executive Committee's action in starting an investigation into Secretary Work's summary dismissal of Mr. Davis, were features of the session Monday and Tuesday of the Board of Direction of the American Society of Civil Engineers, previous to the summer convention being held in Chicago this week. The statement will be read at the business meeting of the society, July 11.

The Board also approved the report of the secretaries of the four founder societies favoring a joint engineering employment service, final approval of the plan to rest with the membership of the four societies. The present employment service is to be discontinued and the joint plan made effective Sept. 1. Branches of the service will be installed in various centers of engineering activity later on.

The Committee on Registration of Engineers was instructed by the Board to present a model law to the Board 30 days in advance of the fall meeting, to be held in Richmond, Va., Oct. 15. Because of his activity in connection with work on the Illinois engineers' license law, T. L. Condron was added to the Committee on Registration of Engineers.

Other action taken by the Board included approval of resolutions expressing regret for the death of Rudolph Hering and John Shoemaker, the latter killed June of last year in the clash between union miners and strike-breakers at Herrin, Ill.; and approval of a petition seeking the establishment of a city planning division of the society. Five technical divisions have now been organized or authorized. Four of these, dealing with the sanitary, highway, irrigation and power fields, were organized at the annual meeting of the society held in New York City Jan. 17-19.

The Board voted to hold the 1924 spring meeting at Birmingham, the summer convention at Pasadena, Calif., and the fall meeting at Detroit.

An analysis of the consumer's dollar, based on November, 1922, prices, shows that in New York every dollar paid for 145 lb. of coal; 56c. of the dollar went to the mine operator, 18c. to the railroads, and 26c. to the dealer. In Washington, the consumer's dollar paid for 141 lb. of coal and was distributed as 58c. as the mine price, 20c. as freight, and 22c. to the dealer. In Chicago, the dollar paid for only 120 lb. and was distributed as 49c. as mine price, 30c. as freight, and 21c. to the dealer.

As so large a part of the consumer's dollar goes to freight charges, the commission recommends that the Interstate Commerce Commission make further investigation of the reasonableness of the present anthracite rate. In view of the three successive jumps of approximately a dollar in the mine price of coal in the past three years, which is largely charged to labor, the commission has undertaken an extensive inquiry into the cost of living, the earnings, and other conditions surrounding the mine workers. The income of a family of five ranges in general from \$1,500 to \$2,000 for those who avail themselves of the opportunity to work the year round.

BASIS OF INCOME

The commission has found itself confronted with conflicting claims as to the basis upon which the rate of income should be reckoned. Cost of reproduction might well be reported as a fact with reference to the plant and equipment, but as the greater part of the investment claimed by the company is in coal-bearing land, reproduction cannot apply to these lands, because the lands cannot be reproduced. Nor is present market value a satisfactory basis, as there is no market for such lands in the accepted sense of the word.

In discussing the relation of production to the increase in population, the commission points out that the most significant fact is the progress made in twenty years in decreasing the wide gap between mine capacity and actual output; with approximately the same number of mine workers, the production was 50 per cent greater in 1920 than in 1900.

On the matter of the miner's rights, the commission says that the principle that a man has a legal right to work free and unpimped and for whomsoever he choose; that another man has a legal right to employ and discharge as he pleases, and that men have a right to bind themselves together for collective bargaining are freely admitted by every one. These principles, honestly lived up to, would keep the open shop and at the same time permit the existence of the unions. But, as a matter of fact, the closed shop in a unionized mine is open to the union miner and closed to the non-union miner, while the open shop in the non-union mine is open to everybody save a United Mine worker. Neither side can show absolutely clean hands in keeping and helping to enforce the civil rights of American citizens.

The commission makes the following recommendations for the prevention of strikes:

"1. The commission recommends that in the next agreement there should be a provision for a continuing umpire and that he or an assistant named by

him should sit with the Conciliation Board at all its meetings, but without a vote.

"2. That alternates should be selected with authority to act in the absence of the original member.

"3. The operators' group should appoint a full-time representative and all necessary assistants to consider jointly with the district officers of the union each case before it is appealed to the Conciliation Board in the hope of securing a local agreement, thus producing a mutual feeling of respect for the other's opinion and each obtaining the outlook of the other upon the problems.

"4. So many changes have taken place since 1903 that the agreement should provide for a joint committee to work out a restatement of the whole agreement in the terms of today, and this agreement should be specific enough to be the code by which all persons having anything to do with the settlement of grievances shall be bound.

"5. If the Board of Conciliation does not clearly understand the facts involved in any case, it should appoint an examiner from each side immediately to investigate and furnish it with all the facts.

"6. The agreement should provide for penalties for the breach thereof by either party, and the method by which such penalties are to be enforced.

"7. The renewed agreements have too rigidly retained the practices and conditions of 1902 and have not had adequate flexibility. A second joint committee should be provided for in the next agreement and directed to make an engineering study of the elements of the job of mining anthracite coal, for the purpose of building up a scientific and more equitable basis for rate making.

"8. The expiration of the contract in the anthracite region should not coincide with the expiration of that in the bituminous region. The contract should run for a definite period of time with the proviso that it shall be deemed to be renewed for a like period of time except as to such provisions thereof in which notice of a desired change shall have been given by either party to the other at least ninety days before the renewal date. Upon these proposed changes the parties shall immediately confer and if, sixty days before the date fixed for the renewal of the contract, they have been unable to agree, they shall report such fact to the President of the United States, specifying clearly the controverted points. The President shall thereupon appoint a person or persons to inquire into and make public a report upon all the relevant facts in controversy before the date of such renewal shall have arrived."

CONCLUSION

In conclusion the commission recommends at this time no punitive legislation. It awaits with interest whether the next agreement entered into shall show a co-operative spirit, a clear idea of partnership on the part of all concerned, and a proper conception of the rights of the American people. It points out that both the operators and the United Mine Workers are giving out information which apparently is intended to inflame the public mind for or against one of the parties, instead of informing the public as to what will be justice to both operator and miner.

Random Lines

Naval Engineering

In commenting on the sabotage of the "Vaterland," now the "Leviathan," former Secretary of the Navy Daniels explains as follows:

"On examination, the complete report by Captain Jessop will show other acts of sabotage, such as the removal of the propeller shafts, which would have permitted the seepage of tons of water into the hull of the ship and thereby cracked in the high pressure cylinder."

The mystery is how the binnacle, the foretopmizz'nm'st and the bos'n all escaped injury.

This Week's Grist

"Read what Henry F. Woods, Secretary of the Forgery Prevention Bureau of New York, has to say as to what the Todd Protograph Co. has accomplished for Business America. Then call a Todd Forgery Prevention Engineer at Seneca 0571. He will gladly give you a visible demonstration of the story."—From a Buffalo newspaper.

Lauterbach, 1826 W. Pratt St. Paint Engineer

A hand bill from Baltimore.

At a recent meeting of the Buffalo City Council the gentlemen who remove the garbage cans from the back doors were referred to as "sanitary engineers."

Sir—"Having noted, in my weekly quota of reading, the advertisements of Smart, Clever, and Sharks as "clothing engineers," I felt thoroughly vindicated, as an "ornery" civil, when I saw the spirit of retaliation manifested in an ad. of the products of a steel works, who emphasized their "hand-tailored boilers." E. F.

Warning Mr. Ashburner

The new city manager of Stockton, Calif., has good cause for action against the make-up man on the Washington *Star* who perpetrated the following sequence of news and philosophy:

NORFOLK, Va., June 23.—Charles E. Ashburner, city manager of Norfolk, and the first man to hold that position in the United States, resigned today to accept the place as city manager of Stockton, Calif., at a salary of \$20,000 a year.

Fortune, when she caresses a man too much, makes him a fool.

Philadelphia Resumes Construction of Delivery-Loop Subway

Bids have been called by the Department of City Transit, Philadelphia, for construction of part of the delivery-loop subway, authorized in 1916 and begun shortly after. The portion to be put under contract includes 1,529 lin. ft. of the Arch St. leg of the loop. It is double-track structure of box section. About 300 lin. ft. of sewer besides intercepting sewers along the sides of the subway are included. Two short sections at each end of this one were constructed in 1917. It is planned to complete subway construction on this side of the loop eastward to a point near Eighth St., where the line is subject to change under revision of the plans now being considered.

As contemplated before the war, Philadelphia subway construction was to include the delivery loop in conjunction with a main trunk line north and south in Broad St., of which, however, only the section under the city hall, all of which forms a station, was built. Recently the administration, after the Frankford elevated line was placed in operation last November, proposed to place under contract a 13,000-ft. section of the Broad St. subway, beginning at a point 7,000 ft. north of the city hall and extending to Venango St. Changes in routing that have been suggested since the work was originally planned would not affect this portion. However, the city council repealed the ordinance appropriating funds for the Broad St. section. The appropriation for the delivery loop through Arch, Eighth, and Locust Sts. was not affected by this repealer. A commission of the council, including representatives of business organizations, is now considering the question of revising the authorized lines. It is working in conference with engineers of the Department of City Transit and of the Philadelphia Rapid Transit Co. The report of this commission is expected to be a necessary preliminary for further subway construction.

Marx Becomes Emeritus Professor at Leland Stanford

Charles D. Marx, professor of civil engineering at Leland Stanford Jr. University (Palo Alto, Calif.), retired at the end of the recent term and became professor emeritus. He went to Stanford in the opening year, has served the institution with great credit, and leaves under the university regulation that retires faculty members at the age of 65. For many years he has been prominent in activities of the Am. Soc. C. E. of which he has served successively as director, vice-president and president. When the San Francisco Engineering Council was organized some years ago to represent all technical societies having branches at San Francisco, Professor Marx was selected as president and each year has been re-elected to that office. A review of his professional record was published in *Engineering Record*, Jan. 23, 1913, p. 124.

C. B. Wing, professor of structural engineering at Leland Stanford Jr. University, becomes head of the civil engineering department. The faculty in this department is to be strengthened by the addition of L. B. Reynolds of the Burns & McDonnell Engineering Co., Kansas City, Mo.

Pennsylvania Soon to Organize State Traffic Police

The vanguard of Pennsylvania's traffic inspection force, authorized in a bill recently signed by Governor Pinchot, will be on the roads within a month, according to word emanating from the State Department of Highways last week. The legislation authorizes the highway commissioner of the state to employ such men as he deems necessary to enforce the penal provisions of the motor laws. Particular attention will be paid to the correction of the following evils, says Paul D. Wright, highway commissioner: Overloading of trucks, excess speed of all motor vehicles, and misuse of headlamps.

It is the intention of the commissioner to drive from the road the five per cent of road users who endanger the lives of all those who travel the highways. As an indication of the problem Pennsylvania faces in the correction of the headlamp evil, it is said that there are 150 different headlamps and devices approved by the department, many of which are declared to be obsolete. Also, there is almost as wide a divergence in the lenses used, so that the combination makes night traveling one of the most difficult of the problems concerned with road traffic in Pennsylvania.

The traffic inspection force is to be uniformed. Those police who will supervise speed of vehicles will use motorcycles, while automobiles will be used by those in the inspection force who are on the lookout for violations of the laws governing truck weights. Scales will be carried by these machines and whenever overloading is suspected, trucks will be weighed.

Kansas Contractor Goes to Work

DURING a recent flood in Kansas, caused by continued excessive rains, several cities were inundated by flood waters from the Arkansas River. Herewith is a photograph of the principal street of Wichita, Kansas, Douglas Ave. Irwin Hale, a general contractor of that city, is en route to his work. The current of the flood waters is considerable, as the picture indicates.

Wisconsin Bill Proposes State Acquisition of Water Power

The Wisconsin Legislature in session at Madison, has before it for consideration a bill which will amend the state constitution so as to permit the state to go into debt, by issuing securities, in order to buy hydro-electric power plants and water-power sites. The bill has passed the lower house and is expected to pass the Senate shortly.

Illinois Central R.R. Completing Chicago Yard

Work is being pushed on the large terminal freight yard of the Illinois Central R.R. at Chicago and it is expected to have the greater part of the yard in service before the end of the year. This Markham yard, just south of Harvey, Ill., 18½ miles from the Chicago passenger terminal, will be the main-line freight terminal for the Chicago district, where inbound trains will be broken up and outbound trains made up. All movements north of this yard will be switching and transfer service. This freight terminal was begun in 1918 (see *Engineering News-Record*, Aug. 15, 1918, p. 313) but work has been delayed by various causes. About \$2,500,000 has been spent, mainly on the filling to raise the site to grade, but \$6,000,000 will be required for completion. For northbound and southbound traffic there will be two separate units, each consisting (for the present construction) of a 10-track receiving yard, a 10-track departure yard and a classification yard with hump for gravity switching. The northbound classification yard will have sixty tracks for 2,400 cars and the southbound yard will have forty tracks for 2,000 cars. Double the number of tracks in each yard is provided for by the general plans. In addition there will be an engine terminal and a transfer station for rehandling i.e.l. freight.

The design and construction of the terminal yard are under the direction of F. L. Thompson, chief engineer, Illinois Central R.R.

Let First Contract on Moffat Main and Pilot Tunnels

The letting of a contract July 5 for electric power (3,000 hp.) for driving the 6-mile Moffat Tunnel under James Peak, just west of Denver, marks the initial step in the expenditure of a bond issue of \$6,720,000 by the Moffat Tunnel Commission. A pole line 29 miles long from the Colorado Power Company's plant 5 miles west of Boulder is to be completed within 90 days and ready to deliver power at both east and west portals. The cost is approximately \$65,000 and the contract price for current will average about 1c. per kw.-hr. When completed traffic through the tunnel will be operated electrically with current over the same pole line.

Successful sale of the 5½ per cent bonds late in June at a premium of \$215,000 followed the action of the U. S. Supreme Court in validating the bonds by decision handed down June 11.

W. P. Robinson, president of the commission, states that he hopes to have the work under contract by Aug. 10 and actual construction started by Sept. 1. A chief engineer and staff will probably have been appointed by the time this is printed. Tunnel contractors have been notified of the work and the public advertisement will be made the latter part of July, a minimum of 10 days only being required.

The commission of five members, who serve without pay, was appointed by the governor immediately after the law went into effect. Their successors were voted upon July 10 but the only nominees were the appointees. D. W. Brunton, J. Vipond Davies and J. Waldo Smith are the consulting engineers.

Missouri Highway Department Loses Freight Rate Suit

The Missouri Public Service Commission July 3 dismissed the complaint filed by the State Highway Commission against all the railroads of the state, demanding a reduction in intra-state freight rates on road building materials. The dismissal was without prejudice to the right of the Highway Commission to apply to the Public Service Commission for specific rates on road building materials between given points within the state.

The commission held that to grant the highway body's request and lower rates for general application between all points in the state upon all shipments of road building materials would result in undue discrimination against interstate commerce in the same commodities, which is prohibited by the interstate commerce act.

A ruling of the Missouri Supreme Court in a similar case against the Missouri, Kansas and Texas Ry. Co., was cited to support this view.

Pinchot Gets Bill Seeking Repeal of Engineers' License Law

Both legislative and judicial opposition to the engineers' license law has been raised in Pennsylvania. Governor Pinchot has now before him a measure seeking the repeal of the registration law, upon which action must be taken by July 13. There is little exact knowledge concerning Governor Pinchot's attitude on the bill, though it is the personal view of a number of engineers of high repute in the state that he will veto the repealer.

Judicial opposition to the bill is embodied in a decision handed down July 2 in a lower court by Judge Samuel E. Shull, of Stroudsburg, who decreed that the 1921 law creating the registration board is unconstitutional. The decision was the result of a test case wherein George D. Stevenson, a civil engineer of Scranton, was arrested about a year ago for practicing his profession without first obtaining a license.

Forty-Year-Old Bridge Destroyed by Colliding Automobile

An old iron truss highway bridge crossing Pushta Creek near Wapakoneta, Ohio, was wrecked on the night of June 2 by an automobile which struck the end post while traveling at high speed. Chalmers S. Brown, of Lima, reports the accident as follows:

"The bridge, built in 1883, was a pin-connected through Pratt truss structure of 88 ft. span, with a clear roadway of 16 ft. The trusses were 15 ft. high and comprised eight panels of 11 ft. The floor was a 2 in. bituminous mat laid on a subfloor of 3 in. oak plank over 3 x 12 in. oak joists spaced 18 in. between centers.

"A large touring car carrying six people approached the bridge from the west at a speed of about fifty miles per hour. The approach to the bridge is on a down grade of 2.3 per cent, and has a curve to the right of 500 ft. radius and 19 deg. central angle which ends 40 or 50 ft. before the bridge is reached. The driver managed to pilot the car into the bridge entrance but in such a manner that the left running board was crushed against the left batter post and the left rear wheel struck the face of this post squarely, knocking the post off the abutment and causing the entire bridge to collapse.

"The speed of the car was such that it reached the last panel of the bridge before the superstructure fell upon it. The line of travel of the car was close to the left-hand guard rail. The top chord of the right-hand truss fell diagonally across the car, crushing the windshield and top and killing one passenger in the front seat and fatally injuring one in the back seat. The damage done to the car by the falling superstructure indicated that the car had come almost to a stop before being struck from above.

"It is interesting to note the heavy floor construction, the estimated weight of which is 42 lb. per square foot or about equal to the total original dead load. The bridge had withstood heavy traffic and was pronounced by engineers safe for ordinary service."

Engineering Societies

Calendar

Annual Meetings

NEW ENGLAND WATER WORKS ASSOCIATION, Boston, Mass.; Annual Convention, Burlington, Vt., Sept. 18-21, 1923.
AMERICAN PUBLIC HEALTH ASSOCIATION, New York; Annual Meeting, Boston, Oct. 8-11.

The San Francisco Section, Am. Soc. C. E. at the bi-monthly meeting on June 19 had as guest of honor Professor C. D. Marx, recently retired from thirty years of active service as head of the civil engineering department, Stanford University. As a token of esteem and in appreciation of his long service, members of the section presented Professor Marx with a pipe banded with gold and suitably engraved. The topic for the evening's discussion was "The Investigation of California's Water Resources."

Personal Notes

DR. GEORGE A. SOPER, consulting engineer, New York City, has been appointed managing director of the American Society for the Control of Cancer. Besides his notable investigations of water treatment and sewage disposal, the latter including years of study while member and president of the Metropolitan Sewerage Commission of New York, Dr. Soper has conducted much epidemiological work, particularly during typhoid outbreaks and while in the office of the Surgeon General, U. S. A., during the World War.

F. D. MARQUEZ has resigned as superintendent of public works in Porto Rico, under the United States Department of the Interior, to become commissioner of public works of the city of San Juan.

FREDERICK L. RANSOME, formerly assistant in geology at Harvard, and since 1913 in charge of sections of western work for the U. S. Geological Survey, has accepted the position of professor of economic geology at the University of Arizona. He is a graduate of the University of California.

A. L. FERVER, for two years director of public service in Long Beach, Calif., has resigned and will be associated with James F. Collins, development engineer, in that city.

JAMES OGDEN has succeeded F. S. Benson as city manager of Bakersfield, Calif.

PROF. IVAN C. CRAWFORD, associate professor of civil engineering at the University of Colorado, will become dean of the college of engineering, University of Idaho, this fall.

R. SCOTT KIFT, civil engineer, Lock Haven, Pa., was elected as borough engineer for Lock Haven to succeed W. F. Cowley, who will locate at Birmingham Ala.

EAST PORTION OF WRECKED BRIDGE

West end post of north truss knocked off abutment and both trusses overturned toward north. Photographs taken from electric railway bridge near.

W. C. KEGLER, engineer of maintenance-of-way on the Cleveland, Cincinnati, Chicago & St. Louis Ry., has been appointed engineer of track and roadway, with headquarters at Cincinnati, Ohio.

RICHARD CASE has been appointed assistant town engineer of Phillipsburg, N. Y., to succeed BERNARD P. MONOHAN, resigned. Mr. Case has been connected with the engineer's office of the town for eight years.

T. E. HUFFMAN, county engineer of Denton County, Texas, in charge of the \$2,000,000 highway program for the past four years, has resigned upon completion of the major portion of the work, and H. T. BREWSTER, resident engineer, has succeeded him.

W. S. BELLOWES, Oklahoma City contractor, and W. H. MACLAY, recently of the Central Contracting Co., Dallas, have opened offices as general contractors at 1217 Kerby Bldg., Dallas, under the firm name of Bellowes-MacLay Construction Co.

EDWIN F. WENDT, of Washington, D. C., has been selected as consulting engineer on valuation for the Toledo, St. Louis and Western R.R. Co.

M. M. LEIGHTON has been appointed chief of the Illinois State Geological Survey, with offices at Urbana, Ill., succeeding F. W. DeWolf who resigned.

R. T. HOYT CONSTRUCTION CO. has been organized in Colorado Springs, Colo., with the following as principal members of the firm: R. T. Hoyt, F. L. Grandon and Paul T. Barrett.

MAJOR A. B. CUTTER, former city engineer of Everett, Wash., has been appointed resident engineer for the recent \$850,000 bond improvement program at Bluefield, West Virginia. The bond election carried on June 19.

W. F. COOPER, of Union Parish, assistant highway engineer of the Louisiana Highway Commission, has been appointed by Governor John M. Parker to succeed Arthur Taylor, of New Orleans, as a member and vice-chairman of the commission.

CLYDE PORTS, consulting engineer, New York City and Morristown, N. J., has been elected vice-president of the New Jersey State Board of Health.

ROY A. KLEIN has been made chief engineer of the Oregon State Highway Commission. Mr. Klein, who succeeds Herbert Nunn, retains the position of secretary of the Highway Commission which he has held for several years. Since the resignation of Mr. Nunn, Mr. Klein has been serving as acting chief engineer of the commission.

THOMAS J. WASSER, former chief engineer of the New Jersey State Highway Department, has been engaged by the Public Service Production Co., a subsidiary of the Public Service Corporation of New Jersey. Mr. Wasser will take charge of all road work in his newest assignment.

R. T. REGISTER and G. E. STONE have established the firm of Stone & Register, consulting engineers and contractors, with offices in Baltimore, Md. Mr. Register has been construction engineer of the Loyola Construction Co., Baltimore, and Mr. Stone has been assistant highway engineer.

ORRIN E. STANLEY, for several years sewer engineer, department of public works, Portland, Ore., has been appointed chief of the bureau of maintenance in that department, following the resignation of R. S. McMullen. C. H. SMITH is the new sewer engineer.

H. L. TROTTER and C. L. CATE have formed a partnership under the firm name of Trotter & Cate, consulting engineers, with offices in Montreal. Henry Holgate will be connected with the firm as associate consulting engineer. Col. Trotter is a graduate of the Royal Military College, Kingston, and has worked with Ross & Holgate, consulting engineers, and for Morrow & Beatty in British Columbia. Mr. Cate is a graduate of McGill University and besides doing hydro-electric work with the Foundation Co., Ltd., has been a consulting electrical engineer.

H. B. VOORHEES, general manager of the New York terminal of the Baltimore & Ohio R.R., has been promoted to be general manager, western lines, with headquarters at Cincinnati.

L. S. ROSE, assistant to the general manager of the Big Four Ry., has been appointed general manager of the Peoria & Eastern, with headquarters at Indianapolis, Ind.

DR. W. R. WHITNEY, director of the research laboratory of the General Electric Co., was recently elected a member of the corporation of the Massachusetts Institute of Technology for a term of five years. CHARLES R. MAIN, consulting engineer, Boston, was also elected to the corporation. Both men are graduates of the school.

THEODORE E. VELTFORT, who for ten years has been assistant to the district construction manager in the Chicago office of Stone & Webster, Inc., has been transferred to the structural division of the company in the Boston office.

HOWARD A. HOLMES, construction engineer of the Montana state highway department, has been appointed chief engineer of the highway commission of that state, succeeding John N. Edy, who has gone to California.

JAMES ALLEN, formerly state highway supervisor of Washington under the department of public works, has now been designated state highway engineer reporting directly to the State Highway Commission.

BERNARD L. CROZIER has been appointed highway engineer for Baltimore, Md., succeeding CHARLES F. GOOB. Mr. Crozier has been connected with the engineering forces of the Baltimore & Ohio R.R., United Railways & Electric Co., Maryland State Roads Commission and the Baltimore Paving Commission.

JOHN A. MACDONALD has been appointed highway commissioner of Connecticut to succeed C. J. Bennett, who resigned July 1 to enter the construction business. E. C. WELDON, former division engineer, has been named deputy commissioner.

The WATSON ENGINEERING CO., Cleveland, Ohio, architects and engineers, has changed its corporate name to the Watson Co., in order that the name of the organization may describe more accurately the scope of the service it gives. The change became effective June 1. For sixteen years the services of the company have consisted mainly of design and supervision of

construction of both architectural and engineering structures. The reconstructed firm offers to its clients coordinated personal services of a competent staff of architects and structural, mechanical, electrical, heating and ventilating engineers, all of whom have had specialized training and experience.

Obituary

JOSEPH G. LEGRAND, bridge engineer of the Canadian National Railways, Western region, died at Winnipeg July 2. He was born in France in 1861 and went to Canada at the age of 30. In 1900 he was appointed bridge engineer of the Grand Trunk Ry. and in 1920 to the position he held at the time of his death.

JOHN A. BRITTON, first vice-president and general manager of the Pacific Gas & Electric Co., died in San Francisco June 29, aged 68 years. He had spent most of his life in California, having gone to that state from Massachusetts at the age of thirteen. His schooling was cut short by the necessity of earning his own way and he entered the employ of the Oakland Gas Co. as collector in 1870, working up through the positions of secretary and chief engineer to the office of president. When the company was absorbed by the Pacific Gas & Electric Co. he again advanced rapidly in the larger field to the position held at the time of his death. As active head of the company he directed the affairs of one of the largest hydro-electric systems west of Chicago. He was an active participant in affairs of the civil, mechanical and electrical societies, and at the time of his death was the president of the Bohemian Club and a prominent leader in business and professional circles.

JULIO FEDERICO SORZANO, consulting engineer, died in Brooklyn, New York, June 25. Educated in France and Belgium, he had been engaged in the engineering field since 1879. Although established in New York, the greater part of his work was done abroad, principally in Cuba, Mexico, Puerto Rico, Haiti and the countries of South America. He designed and built a score or more sugar mills in Cuba and Puerto Rico alone, and was an acknowledged expert in matters pertaining to the raw cane and beet root sugar industries. He constructed the first railway built in Venezuela, as well as two subsequent roads in the same country. One of the first matters on which he was consulted here was in connection with the foundations of the Brooklyn Bridge towers with which there had been considerable difficulty. He was greatly interested and very active in the Panama Canal controversy over the relative merits of the lock canal as against the sea level canal, and the water supply available for the lock canal. Mr. Sorzano was a close student of Latin-American affairs, and in 1911 organized the Pan-American Chamber of Commerce. He was president of the institution up to the recent illness which culminated in his death. He was a member of the American Society of Civil Engineers, the American Society of Mechanical Engineers, the Institution of Civil Engineers of Great Britain and la Société des Ingénieurs Civils de France.

From the Manufacturer's Point of View

A Point of Contact
Between Maker and User of
Construction Equipment and Materials

Lubrication of Construction Equipment—Part II

How Contractors Can Secure the Maximum Service from Gears, Chains, Wire Rope and Concrete Mixing Machinery

(From Information Supplied by The Texas Co., New York.)

IN ORDER to preserve and maintain operation at the highest efficiency, it is essential to keep all gears, chains and wire rope well coated with a suitable compound which will serve not only as a lubricant, but also as a preservative. Wire rope in particular requires attention due to the possible hazard involved if internal strands are allowed to rust, wear and corrode. Although wire rope as constructed today contains a hempen core which is usually soaked in lubricant prior to the winding of the steel strands, the theory that this core will serve adequately to lubricate the strands and prevent wear, rust and corrosion during subsequent service should not be relied upon. Therefore, the exterior surface of the rope should be treated at frequent intervals with a suitable lubricant and preservative, which is capable of penetrating to the innermost strands during operation and not only re-lubricating the core but as well preventing wear at the points of contact of the strands.

Such a compound should be: Plastic at all temperatures; capable of being readily applied in a thin film without undue heating; free from acids and alkalis; non-evaporative; so tenacious and adhesive as not to drip or run off under abnormal pressures or temperatures; insoluble in water; non-hardening; capable of resisting the entry of dust, dirt, chemical fumes or salt water. The most suitable lubricant for this service is a pure petroleum compound having a viscosity of about 2,000 Saybolt at 210 deg. F. In some cases increased viscosity up to perhaps 5,000 may be necessary.

Gears and chains should be treated with a similar compound. There is relatively no hazard if they are neglected, but wear will develop abnormally accompanied by excessive noise and rattling, and corrosion of the wearing surfaces, especially if they are exposed to sea air, or acid fumes. Whatever the type of machine involved, the setting and aligning of gears is important, and all teeth should so mesh that there will be a uniform and constant application of power and smooth, quiet operation in order to insure against jerky action. This latter would tend to produce strains and abnormal wear, not only on the gears, but also on other driving mechanisms.

To attain best results in applying the gear lubricant the surfaces of all teeth should first be washed with kerosene or some other solvent, the lubricant being then heated and brushed or poured lightly onto the wearing surfaces while the gears are in slow rotation. Pressure between the teeth will adequately spread the lubricant, if it is applied in the proper amount, and

it should not be forced over the sides of the gears unless the film is too thick. In this event the intensity of the application should be decreased.

CONCRETE MIXING MACHINERY

In construction work concrete mixers have become essential. Their rate of production is the prime factor governing the progress of the work, and possibility of break-down due to serious wearing of gears, overheated bearings or engine troubles which are traceable to faulty lubrication, should be carefully guarded against. Concrete mixers, at best, will receive the roughest kind of treatment. There is always a certain amount of dust grinding into bearings, gear teeth or other operating mechanisms, so that mixers should receive proper and sufficient lubrication throughout the job.

In general the lubrication of concrete mixers, whatever their type or design, can be effectively carried out by the use of three grades of lubricants: A gear compound; a suitable grade of grease or semi-solid lubricant for general bearing lubrication; and a power plant lubricant adaptable to the type of machinery used to drive the mixer. On gears, pinions, racks, sprocket wheels and chains, as well as wire rope, a heavy grade of petroleum compound having a viscosity of about 2000" Saybolt at 210° F. has proved to be the most dependable lubricant. Such gearing in general operates under considerable pressure and there is always a certain amount of dust, slush and water present. Therefore, a lubricant must be selected that will not only have sufficient viscosity to insure a dependable film and prevent metal to metal contact, but as well which will be so adhesive as to stick to the teeth and chains and resist the washing action of water as much as possible.

Grease or cylinder oils can be used on such gears but they are not as efficient as the heavier compound due to the presence of dust and to their tendency to absorb or accumulate fine particles of cement readily. They simply develop into an abrading paste instead of a lubricant. The heavier compound mentioned above, however, withstands such contamination to a marked extent.

DRUM ROLLER BEARINGS

The bearings of drum rollers also require careful lubrication if the machine is to be kept in continuous service and breakdowns forestalled. If these bearings are not properly lubricated at all times the resultant wear, which will be brought about by the abnormally high down-thrust caused by

the tumbling action of the materials within the drum, will result in flattened shafts and a certain amount of wobbling. Vibration, pounding, and distortion or misalignment of the entire mechanism will thereby follow. Certain manufacturers use roller bearings on the drum rolls, and certain other shafting, while others prefer split babitted bearings equipped with grease cups.

ATTENTION TO GREASE CUPS

Where roller-bearings are used the most suitable lubricant will be a pure mineral product of the nature of petroleum, a relatively heavy grade of liquid grease or a light compression cup grease. Grease cup service requires a heavier lubricant of about the same consistency as a medium compression cup grease. Attention to grease cups throughout the machine is very important. In daily operation they should be kept well filled with clean grease and screwed down at least twice a day in order to insure a sufficient film of lubricant in the bearings to prevent cement dust from working its way in along the shaft ends.

Roll surfaces and drum runways should never be lubricated, inasmuch as the presence of oil or grease on the frictional surfaces will reduce tractive effort. Such rolls are in general built of car-wheel metal in order to withstand the heavy duty required.

Lubrication of the power plant of a concrete mixer will, of course, depend upon its type. Where steam is used both internal (or cylinder) and external lubrication are required. Inasmuch as saturated steam is chiefly used, a compound steam cylinder oil of from 130 to 150" Saybolt viscosity at 210° F. will be suitable. This should be furnished to the cylinder at a rate of about five drops per minute by means of a dependable hydrostatic or force-feed lubricator. Care of a hydrostatic lubricator is important especially in freezing weather. During such operation whenever a shutdown is to be made for any length of time, both oil and water should be drained from the lubricator, in order to prevent freezing in the sight feed glass, and possible cracking.

EXTERNAL ENGINE LUBRICATION

The external lubrication of engine bearings and guides, etc., should be carried out in the manner explained heretofore, using either a high grade straight mineral oil suitable for service in ring oiling systems and drop feed oil cups, or a pure compression cup grease of light or medium grade according to the prevailing temperature involved. In general, grease lubrication is preferred by most mixer builders and their machines are therefore usually equipped with compression grease cups.

Where internal combustion engines or electric motors are used to drive the mixer lubrication is similar to that recommended for excavating machines equipped with similar power plants. All such machinery is subjected to the same severity of operation. Hence, motor bearing lubricants of from 180 to 200" Saybolt viscosity at 100° F. will be most suitable on electric drive mixers; and the usual grades of automobile and tractor engine lubricants will serve the purpose on internal combustion engines.

Messinger Becomes President of the Chain Belt Co.

C. R. Messinger, vice-president and general manager of the Chain Belt Co., Milwaukee, since 1917, has been appointed president, succeeding William C. Frye who retires from active participation in the company's affairs after a service of 28 years with the organization, including 7 years as its administrative head. Under Mr. Frye's leadership the company has maintained a steady growth, inaugurated by C. W. Levally, founder and first president, in the production of chain, concrete mixers and conveying machinery, under the trade name of Rex.

Mr. Messinger joined the Chain Belt organization in 1917 after 8 years as general manager of the Sivy Steel Casting Co. He is also president of the Interstate Drop Forge Co., vice-president of the Sivy Steel Casting Co., vice-president of the Federal Malleable Co., all of Milwaukee, and a director in the Nugent Steel Castings Co. of Chicago and the First Wisconsin National Bank of Milwaukee. During the term 1922-23 Mr. Messinger was president of the American Foundrymen's Association and is also prominent in the affairs of the American Malleable Castings Association.

Recommend Fewer Varieties of Structural Concrete Units

Washington Correspondence

Recommendations for the elimination of a number of sizes of structural and partition units made of concrete were endorsed by committees representing the Concrete Products Association and the American Concrete Institute at a preliminary meeting held in Washington, D. C., June 21 with the Division of Simplified Practices of the Department of Commerce. The committees expressed a desire for a general meeting of all interests concerned in the subject next October to consider adoption of the recommendations.

The tentative recommendations are the result of a survey made under the direction of Wallace R. Harris, chairman of the Committee on Standard Building Units of the American Concrete Institute. This survey showed concrete blocks made in 30 different lengths, 20 widths and 26 heights.

The tentative recommendations for foundation units are: Height, 7½ in., length, 15½ in., with wall thicknesses of 8 and 12 in. For load bearing wall units the recommendations are: Height, 7½ in., length 15½ in., and wall thicknesses of 6, 8, 10 and 12 in. For load bearing concrete structural tile the recommendations are: Height, 5 in., length, 11½ in., and wall thicknesses of 4, 8 and 12 in. For concrete partition tile (non-load bearing) the recommendations are: Height, 7½ in., length 16, 18 and 24 in., and width 3, 4, 6 and 8 in.

Attending the preliminary conference were: Herbert A. Davis, representing both the Concrete Products Association and the American Concrete Institute; C. E. Lindsley, American Concrete Institute; L. L. Wagner and John L. Miner, Concrete Products Association; P. E. Holden and E. W. McCullough, Chamber of Commerce of the United States; and R. M. Hudson, assistant chief of the Division of Simplified Practice.

George L. Buff, Instrument Maker, Dies

Head of Well Known Firm Began Work at 17 in German Shop and Established Own Business in New York in 1870

GEORGE L. BUFF, head of the Buff & Buff Manufacturing Co., which for years has supplied surveying instruments for notable engineering projects throughout the world, died July 5, at the age of 84. Such works as the Panama Canal, the Catskill Aqueduct, the Union Pacific, New York, New Haven & Hartford, and Mexican Central Railways, to say nothing of thousands of triangulation surveys and scores of long tunnels, mines, highways and waterways have depended for their location, alignment and precise control of line and grade on the transits and levels

produced by the organization established by Buff in Fulton St., New York, in 1870, and later moved to Boston.

Born in Giessen, Germany, in 1839, of the family which furnished Goethe with the *Lotte* (Charlotte Buff) for "Werther's Leiden," George L. Buff left home at the age of 17 to enter the factory of Repsault & Co., Hamburg, manufacturers of scientific instruments. Two years later he went to York, England, as foreman in charge of the large astronomical instrument shops located there. For six years he devoted his efforts to the finest sort of mechanical workmanship and with this training as a foundation emigrated to New York in 1864 to associate himself with the firm of Stackpole & Sons, well known instrument makers.

BUSINESS ESTABLISHED IN 1870

In 1870 he established his own business on Fulton St., New York, and a year later entered into a partnership with C. L. Berger under the firm name of Buff & Berger, which continued 27 years, and won a nation-wide reputation for the excellence of its products. This partnership was dissolved in 1898 when Mr. Buff took his three sons into a newly formed organization under the name of the Buff & Buff Manufacturing Co., with a manufacturing plant in Boston.

Speaking of his work, one of his friends has said: "Buff made beautiful instruments for the love of it; he was indifferent to wealth. He created designs to fulfill certain requirements and brought them into being with unexcelled faithfulness and accuracy of workmanship. The sturdy beauty of his designs, their consistency of proportion and their extreme and faithful accuracy made his instruments world-famous. Even after his organization had expanded he insisted upon personal supervision of the individual construction of each instrument manufactured."

CHARLES CLIFTON, of the Pierce-Arrow Co., was re-elected president of the National Automobile Chamber of Commerce at the annual meeting in New York, June 7.

Business Notes

A. F. MCCLINTOCK has been appointed assistant sales manager of the Reading Iron Co., Reading, Pa.

BUCYRUS Co., South Milwaukee, Wis., manufacturer of power shovels, and excavating and dredging equipment, announces the appointment of E. J. Wilkie as northern sales manager, succeeding E. R. Weber, resigned. Mr. Wilkie will have general charge of the sale of Bucyrus products in Wisconsin, Minnesota, North and South Dakota, Michigan and Montana, with headquarters in South Milwaukee.

E. M. BREED, for several years assistant manager of sales for the Pelton Water Wheel Co., San Francisco, has been appointed sales manager with headquarters in San Francisco. Mr. Breed has had a wide experience in hydro-electric work, having been connected with the Pelton company in various capacities for the past fifteen years.

CHAMPION ENGINEERING Co., Kenton, Ohio, has opened a new sales office in Chicago to take care of increasing business in the crane and caterpillar sluice gate lines. This office will be in charge of W. B. McCracken, transferred from the company's operating department to the sales department.

Equipment and Materials

Pick-up Motor Street Sweeper Has Gutter Cleaning Attachment

A one-man motor-driven pick-up street sweeper with auxiliary gutter cleaning attachment and water sprinkling system has been designed by the Foamite-Childs Corp., Utica, N. Y., and machines of this type are already in service in the cities of Augusta, Ga.,

Elmira, and Massena, N. Y. The equipment consists of a rotary broom 32 in. in diameter and 6 ft. wide mounted at the rear of a Reo speed wagon and delivering into an inclined conveyor which discharges into a closed storage hopper of 50 cu.ft. capacity. Tests have indicated that the machine operates most effectively at a speed of 9 miles per hour.

The rear broom is built up on a grooved wooden core, with end castings to protect the fiber, and is filled with either steel or split bamboo. As the broom wears, the distance between broom and conveyor is automatically shortened to insure uniformity in the delivery of street dirt to the conveyor.

The conveyor drive is equipped with wood shear pins which break at the entry of any large heavy object which might foul the machine. The broom also stops when the shear pins break. The conveyor is of the rubber squeegee type with removable bottom. The dirt storage hopper has a smooth interior, without shelves or bridges, so that dumping can be done quickly and completely.

The gutter broom at the side of the machine works automatically in and out along the curb, brushing the dirt out under the sweep where it is caught by the large broom at the rear. The gutter broom has a steel fiber filling 42 in. in diameter built in six segments that are easily removed and replaced when the broom wears. A feature of the sweeper is that both rear and gutter brooms may be made to revolve while the sweeper stands still.

The water sprinkling system in front of the machine consists of a 150-gal. galvanized iron tank with brass strainers at intake and outlet from which water runs by gravity to a rotary gear pump that forces water to the nozzles.

Roller Bearing I-Beam Trolley

A combination of strength and flexibility was sought in the design of the steel-plate, roller-bearing I-beam trolley which the Yale & Towne Manufacturing Co., Stamford, Conn., has placed on the market. The equipment, as shown in the illustration, consists of a pair of flanged wheels attached to side plates from which a shackle plate is supported by a single equalizing pin. The trolley has a rated capacity of 2 tons, although under test it has sustained a load of 14 tons. To each side plate are riveted spreader bearings which give a large bearing surface for the equalizing pin and are so shaped as to protect the trolley and act as a bumper which engages the track stop on the lower flange at the end of the I-beam track. The axles are set at the same angle as the surfaces of the I-beam flanges and are pressed into wheel hubs and supported by inner bearing plates subjected to practically no bending strain.

The non-rigid construction of this trolley, its manufacturer claims, allows it to pass around a curve of sharp degree without binding.

Publications from the Construction Industry

Caterpillar Type Mounting—ERIE STEAM SHOVEL CO., Erie, Pa., has issued a 20-p. illustrated bulletin featuring its lubricated caterpillar type mountings for power shovels. The lubrication system is explained in detail and another feature emphasized is the use of removable bushings on the link pin bearings.

Wood Preservation—C. A. WOOD PRESERVER CO., St. Louis in a 44-p. booklet

entitled "Evidence" presents data indicating the effectiveness of its carbolicum treatment to prevent rot and decay of timber. A number of testimonial letters indicate the value of wood preservation in a variety of uses.

Motor Vehicle Statistics—NATIONAL AUTOMOBILE CHAMBER OF COMMERCE, New York, has recently published the 1923 edition of its "Facts and Figures of the Automobile Industry," a book of 96 pp. illustrated. The publication contains a considerable amount of data of interest to highway engineers and contractors, covering the registration of motor vehicles, annual production of trucks and passenger cars, notes on

motor vehicle taxation, mileages of federal-aid roads, motor vehicle revenue and similar statistical data.

Reinforced-Concrete Pipe—LOCK-JOINT PIPE CO., Ampere, N. J., in a 12-p. illustrated pamphlet, presents details of its three types of joint: Lead and iron; lead and steel; and copper. The text is supplemented by detail drawings.

Portable Hoists—SULLIVAN MACHINERY CO., Chicago, has issued two new bulletins, one on its single-drum and the other on the double-drum Turbinaire portable hoists for scraper loading. These are reprints of earlier editions to which new matter has been added.

Business Side of Construction

FACTS AND EVENTS THAT AFFECT COST AND VOLUME

To Survey Seasonal Operation in Construction Industries

Savings, not only to the building industry and its workers, but to the public generally are expected to result from the activities of a committee on seasonal operation in construction industries, the appointment of which by Herbert Hoover, chairman of the President's Conference on Unemployment, has been announced by the Department of Commerce. This saving should be reflected in lower relative cost of dwellings and other buildings. The members of the committee are:

Ernest T. Trigg, manufacturer, Philadelphia, chairman; John W. Blodgett, manufacturer, Grand Rapids, Mich.; John Donlin, president, Building Trades Department, American Federation of Labor, Washington, D. C.; L. F. Eppich, president, National Association of Real Estate Boards, Denver; A. P. Greensfelder, contractor, St. Louis; John M. Gries, Department of Commerce, Washington, D. C.; Otto T. Mallory, public works expert, Philadelphia; Rudolph P. Miller, engineer, New York; James P. Noonan, president, Brotherhood of Electrical Workers, Washington, D. C.; William Stanley Parker, architect, Boston; and Edward Eyre Hunt, secretary. The committee at a meeting this week expects to lay out plans for a thorough study of the facts.

Previous surveys have indicated that most construction activity is concentrated in seven to ten months of the year, which means that building trades workers can not find work in their trade during several months, and that contractors' organizations and equipment, architects, engineers, building material producers, and others connected with construction, must usually remain idle for similar periods. This idle time represents waste and direct losses to the construction industries themselves, their workers, and the public.

The committee was formed in the hope that by examining the facts and proposed remedies it might be able to suggest sound solutions and obtain general co-operation in effecting them. It is the general impression that seasonal building has been due perhaps more to custom than to weather, and it is expected that the investigation will throw light on this and other points.

Weekly Freight Loadings Pass Million Mark Four Times

For the third consecutive week and the fourth time this year, according to the Car Service Division of the American Railway Association, loading of revenue freight exceeded the million mark for the week ended June 23, the total for the week being 1,002,740 cars. Freight loading so far this year has been the heaviest in history. The total for the week of June 23 was an increase of 13.6 per cent, or 136,419 cars, over the corresponding week last year, and an increase of 227,293 cars over the corresponding week in 1921.

The total freight car loadings for this year (up to June 23) have been 22,991,055, as compared with 19,157,422 for the same period in 1922.

Large Contracts Let During Week

Among the week's announcements of contracts awarded in Construction News, pp. 11 to 28, are the following: Office and sales building, Chicago, Ill., to Wells Bros. Construction Co., \$8,000,000.

Hotel, Seattle, Wash., to Grant-Smith Co., \$3,000,000.

Apartment hotel, Minneapolis, Minn., to Standard Home Bldg. Co., \$1,300,000.

Dam and power house, Glens Falls, N. Y., to Parklap Construction Co., \$1,000,000.

Power plant, Cahokia, Ill., second unit, to Fort Pitt Steel and Iron Works, Pittsburgh; two 40,000 hp. turbines, one to Westinghouse Electric and Manufacturing Co., East Pittsburgh, and the other to General Electric Co., Schenectady, cost of both, \$1,000,000.

Store and theater, St. Louis, Mo., to Mississippi Valley Steel Co., and Ben Hur Erecting Co., \$1,000,000.

Bids Wanted on Big Jobs

Among the projects on which bids are either asked or will soon be called for, in Construction News, pp. 11 to 28, are:

Store addition, Newark, N. J., for Goerke Co., \$5,000,000.

Temple, Louisville, Ky., for Kosairs Association, \$1,750,000.

Sanitarium, Ft. Worth, Tex., for Methodist Conference, \$1,000,000.

Office building, Toronto, Ont., for Manufacturers' Life Insurance Co., \$1,000,000.

CONDITIONS OF MATERIALS STOCKS IN IMPORTANT CENTERS

Stocks on hand in approximate figures, example: (Lumber, Minneapolis, 60,000,000 to 75,000,000 ft.); time required for delivery of material lots to city job, example: (hollow tile Atlanta 4 to 5 days); and stocks on hand in general terms, example: (brick, New York, scarcity.)

	San Francisco	Los Angeles	Denver	Minneapolis	Detroit	Cincinnati	New Orleans	Atlanta	New York
Sewer pipe.....	Large reserve stocks	Enough, no large surplus	Del. 24 hr., local plant	Situation easier	Plenty	Sufficient	Equal to demands	Del. take 4 to 5 days	Small reserves in city
Cement.....	Stocks low	Scarcity increasing, due to demand	Normal	Ample	Immediate del. from nearby mills	Scarce	Ample	About 50 to 75 cars	Stocks in city small; in 11 shipments quick
Lime.....	Fairly well supplied	Enough, no shortage	Sufficient	Del. from mill on short notice	Plenty in warehouse; del. good	Plenty	Abundance	About 75 cars	Dealers' stocks small; mill del. prompt
Common brick....	Plenty	Sufficient for all demands	4,000,000 to 5,000,000 on hand	Plenty in yards	Fairly supply in local yards	Enough	Plenty; demand showing up	Plenty	Scarcity
Hollow tile.....	Stocks in good condition	Strong demand, stocks holding out	Stocks normal	Dealers' stocks ample	Small stocks	Supply ample	Dealers' stocks sufficient	Del. take 4 to 5 days	Limited stocks in city; prompt del. from nearby plants by water
Lumber.....	Plenty; shipments heavy	Heavy shipments rec'd; no shortage	Mill deliveries easier	60,000,000 to 75,000,000 ft. in yards	Stocks increasing; demand decreasing	Dealers' stocks sufficient	Stocks low, demand slower	Plenty	Del. take 6 to 7 weeks from mill
Asphalt.....	Large native reserves	Demand steady; supply well maintained	About 10 cars	Plenty	Small reserve. Shipments as wanted		None in stock	50 to 100 cars	Heavy reserve, N. J.
Structural steel...	Bar stocks large; structural, fair, low on certain sizes	Mill deliveries take about two months	Warehouse stocks sufficient	Situation easier	Ankle supply for immediate local needs	Difficulty in getting mill del. on bars	Enough; demand lessening with advance of season	6 to 8 cars on sidings	Mill shipment continue heavy

Production and Materials Stocks in Nine Cities

Steel and Lumber Demand Lessened—Output Slowing Down—
Fewer Brick Available—Cement Scarce in Spots

Iron and Steel—The June pig-iron output averaged 122,280 gross tons per day as against 124,764 during the preceding month. This rate represents a falling off of nearly 2 per cent from the May average, which was the heaviest recorded in the history of the industry.

Steel mill operations are proceeding at about 85 per cent of capacity or slightly under the May production rate. Hot weather and labor shortage will probably cause further reduction in the July ingot output. Steel stocks have been restored to normal volume but with considerable falling off in new business, particularly in fabricated structurals.

Unfilled steel tonnage figures issued by the U. S. Steel Corporation, totaled 6,386,261 tons on June 30, against 6,981,351, May 31; 7,288,509, Apr. 30; 7,403,332, Mar. 31; 7,283,989, Feb. 28, and 6,910,776 on Jan. 31, 1923.

The following table shows steel ingot production in gross tons for the first half of the current year, compared with the corresponding period in 1922, as reported by the American Iron and Steel Institute:

	1923	1922
January.....	3,644,629	1,593,482
February.....	3,294,264	1,745,022
March.....	3,858,675	2,370,751
April.....	3,760,997	2,444,513
May.....	4,000,695	2,711,141
June.....	3,574,567	2,634,477

Total 6 months..... 22,133,827 13,499,386

Lumber—Production stands at about 4 per cent above normal or a trifle under the level prevailing one month ago. Shipments represents 104 per cent and orders, 79 per cent of normal production. One year ago production was 10 per cent below normal; shipments, 97 per cent and orders, 84 per cent of normal production. The present situation is one of slight reduction in output but a heavy falling off in both shipments and demand. The following table shows lumber movements during the four weeks ending June 30, compared

with the preceding four weeks:

	Four Weeks Ending—	
	July 30	June 2
	ft.b.m.	ft.b.m.
Cut.....	1,054,593,013	1,102,856,280
Shipments.....	955,820,785	1,035,352,851
Orders.....	767,262,177	857,074,302

Cement—Stocks on hand throughout the entire country June 1, totaled 10,115,000 bbl., as against 12,893,000 for the corresponding period in 1922, according to the Geological Survey. Production amounted to 12,910,000 bbl. during May, compared with 11,176,000 for the same month last year. Shipments totaled 14,257,000 bbl., against 12,749,000 during May, 1922. Compared with a year ago, the cement situation is one of increased production, and still more greatly increased shipments, leaving reserve stocks at mills over 2,000,000 bbl. under the amount on hand June 1, 1922.

Brick—Burned brick on hand totaled 137,520,000 as of June 1, compared with 150,316,000 for the month preceding, according to the Common Brick Manufacturers' Association of America. Orders on books decreased 25 to 50 per cent, compared with the May 1 record, in all districts except two, located in the Middle West. No slackening in production is anticipated unless there occurs a much greater cut in new business than has yet appeared.

San Francisco—Fairly heavy stocks of triangle mesh, expanded metal lath, track supplies and lime. Stocks low on cement, rivets, blue annealed steel sheets and certain sizes of steel structurals. Large reserves of asphalt, road oils, sewer pipe and steel bars; plenty of railway ties, cut nails and common brick. Dealers' reserves of crushed stone, hollow tile, galvanized steel sheets and explosives in good shape; stocks of black steel sheets and wire nails, however, in poor condition.

Los Angeles—Enough sewer pipe but no large surplus. Increased scarcity of cement, due to heavy demand, causing

anxiety among builders and contractors. Cement mills increasing output. No shortage of any other materials.

Denver—Between 4,000,000 and 5,000,000 burned brick on hand, against 500,000, one month ago. Lumber production exceeding demand.

Minneapolis—Situation easier in all materials. Dealers, generally, report stocks of brick, tile and cement in good condition. Lime not kept in large quantities in dealers' warehouses but shipped in from mills on short notice. Lumber stocks normal for season with 60,000,000 to 75,000,000 ft. in Twin City yards.

Detroit—Plenty of all materials except hollow tile and asphalt. Large deliveries of tile available on five to six days notice; small supplies in stock. Asphalt shipped from refineries as wanted; dealers' reserves small.

Cincinnati—Scarcity of cement; other materials plentiful. Difficulty experienced in obtaining mill deliveries on reinforcing bars.

New Orleans—Lumber demand somewhat lessened; stocks low. Abundance of other materials due to slowing up of demand as summer advances.

Atlanta—About seventy-five cars of lime; between fifty and one hundred cars of asphalt; from fifty to seventy-five cars of cement and from six to eight cars of steel structurals, now on sidings. Plenty of brick and lumber. Sewer pipe and hollow tile deliveries take four to five days from mill.

New York—Scarcity of brick continues. Brickyards are unable to keep abreast of demand, owing to fuel and transportation difficulties encountered last year and labor disturbances occurring during the current season. Building materials dealers maintain small local stocks because of limited space; quick mill deliveries by rail and water are depended upon to supply the market. Therefore, a shortage at the mill rather than at the warehouse, would seriously affect the New York builder.

Decrease in Brick Orders

Current reports from brick manufacturers from all parts of the country, according to the monthly statement issued July 1 by the Common Brick Man-

ufacturers' Association of Cleveland, show that there is a general decrease in orders on books. Only two districts show gains over the previous month, and all others are from 25 to 50 per cent below the May record. In the Illinois, Indiana and Wisconsin district, influenced very largely by figures from Chicago, orders on books have been increased by 15,000,000 bricks since last month. Nebraska, Iowa, Kansas and Missouri also report an increase in orders. The latter states were among the last to show evidences of the building tide of the present year.

There has been no slackening in production, the manufacturers report, and there probably will be none until there is a greater cut in new business than has yet appeared. The price remains stable, Chicago continuing to be the minimum price market with brick at \$12 per thousand delivered on the job. New York has the highest price, due, according to manufacturers, to heavy delivery and towing charges and dealers' profits. New York, it is pointed out, is the only large building center where the entire supply of common brick is handled through dealers.

Summer Dullness in Lumber

With production at 261,887,887 ft., shipments at 238,716,310 ft. and orders at 180,939,467 ft., there were further seasonal recessions in the nation's lumber movement in the week ended June 30, according to reports from 385 of the leading mills of the country as compared with 422 mills the week before, says the National Lumber Manufacturers' Association, but they were about what the customary seasonal curve would indicate. Production and shipments were above the 1922 rate.

Weekly Construction Market

THIS limited price list is published weekly for the purpose of giving current prices on the principal construction materials, and of noting important price changes on the

less important materials. Moreover, only the chief cities are quoted. Valuable suggestions on costs of work can be had by noting actual bidings as reported in our Construction News section.

The first issue of each month carries complete quotations for all construction materials and for the important cities. The last complete list will be found in the issue of July 5; the next, on Aug. 2.

Steel Products:	New York	Atlanta	Dallas	Chicago	Minneapolis	Denver	San Francisco	Seattle	Montreal
Structural shapes, 100 lb.....	\$3.64	\$4.30	—\$4.30	\$3.40	\$3.55	\$4.20	—\$3.60	\$4.10	\$4.25

Common labor, non-union, hour.....30	.30@.50	.82 $\frac{1}{2}$.55	.35@.50	.50	.50@.62 $\frac{1}{2}$.30@.35

Explanation of Prices:—Prices are to contractors in carload lots unless other quantities are specified. Increases or decreases from previous quotations are indicated by + or — signs. For steel pipe, the prevailing discount from list price is given: 45-5% means a discount of 45 and 5 per cent. Charge is 15c. per 100 lb. for cutting reinforced steel into 2-ft. lengths or over.

New York quotations delivered, except sand, gravel and crushed stone, alongside dock; common lump lime, in 250-lb. bbl. net, and hydrated lime f.o.b. cars; tile "on trucks"; linseed oil and cast-iron pipe f.o.b. Labor—Concrete laborers' rate, 93c.; building laborers (pick and shovel men) 75c. per hr.

Chicago quotes hydrated lime in 50-lb. bag; common lump lime per 180-lb. net. Lumber delivered on job.

Minneapolis quotes on fir instead of pine.

Brick, sand and hollow tile delivered. Cement on cars. Gravel and crushed stone quoted at pit. We quote on brown lime per 180-lb. net; white is \$1.80 for Kelly Island and \$1.70 for Sheboygan. Common labor not organized.

Denver quotes on fir instead of pine. Cement "on trucks"; gravel and sand at pit; stone on cars; lime, brick, hollow tile and lumber on job. Tile price is at warehouse. Linseed oil, delivered, in iron bbl. Common lump lime per 180-lb. net.

Atlanta quotes sand, stone and gravel per ton instead of cu.yd. Common lump lime per 180-lb. net.

Dallas quotes lime per 180-lb. bbl. Steel, cement, cast-iron pipe and crushed stone f.o.b. cars, other materials delivered.

San Francisco quotes on Heath tile, size 5 $\frac{1}{2}$ x 8 x 12. Prices are all f.o.b. warehouses except C. L. pipe, which is mill price

plus freight to railway depot at any terminal. Common lump lime per 180-lb. net. Lumber prices are to dealers in yards at San Francisco, for No. 1 fir common.

Seattle quotes on Douglas fir (delivered) instead of pine. Lump finishing lime per 180-lb. net. Hollow building tile delivered. Hydrated lime in paper sacks. Sand and gravel at bunkers.

Montreal quotes on pine lumber. Sand, stone, gravel and lump lime per ton. Cement, lime and tile are delivered; sand, gravel and stone on siding; brick f.o.b. plant; steel and pipe at warehouse. Hollow tile per ft. Cement price is in Canadian funds (the Canadian dollar stands at 97.20). Bag charge is 80c. per bbl. Discount of 10c. per bbl. for payment within 20 days from date of shipment. Steel pipe per 100 ft. net; 2 $\frac{1}{2}$ -in., \$32.76; 6-in., \$108.

Changes Since Last Week

Slight weakening in steel warehouse quotations is beginning to appear, consequent to recent concessions in mill prices, due to lower costs of iron and a lessening in demand for steel. Dallas reports a reduction of 20c. and San Francisco, 35c. per 100 lb. on structural shapes. Plates and shapes are holding steadily at \$2.50 per 100 lb. at Pittsburgh mill on the majority of orders. Base price of bars still \$2.40. Demand has been more active in plates and structurals in the last two weeks than during the two weeks preceding. Tank construction is taking the bulk of the

plate business, with railroad requirements next in order of heavy buying.

The June pig-iron output was nearly as heavy as the month preceding, despite hot weather. The third-quarter buying movement, however, is not developing according to expectations and there is a tendency to shade pig-iron prices to points but slightly above the cost of production.

Lumber prices show downward tendencies in several important centers, consequent to a falling off in demand. New York quotes a reduction of \$1 and Dallas, \$2.75 per M. ft. on yellow pine

timbers, while still heavier reductions occurred in Denver and Montreal on Douglas fir.

Linseed oil dropped 1c. in Chicago; 3c. in Dallas and 5c. per gal. in Minneapolis and Denver, during the week.

Common brick is quoted at \$20@21 per M. wholesale, alongside dock, New York, as against \$20 since the first of the year. Cement is also firmer at \$2.80 per bbl. delivered, without bags. Pine lumber, however, declined \$1 per M. ft. on structural timbers.

Cement advanced 11c. per bbl., July 9, in Duluth, Minneapolis and St. Paul.

ENGINEERING NEWS-RECORD

DEVOTED TO CIVIL ENGINEERING
AND CONTRACTING

E. J. MEHREN, Editor
FRANK C. WIGHT, Managing Editor

Volume 91

NEW YORK, JULY 19, 1923

Number 3

Work for Engineering Societies

THE resolution on the Davis dismissal adopted by the American Society of Civil Engineers last week is a good start on the campaign of protest that engineers should get going as soon as possible. Washington officials are not altogether deaf to organized expression of opinion, even though it does come from a group so little political minded as the engineers. By the time he gets back from Alaska Secretary Work should have on his desk the protest of every one of the hundreds of engineering societies of the country. This is a situation where mass and distribution will have the most effect. Not only should the Secretary be impressed with the separate protests but each society would do well to take up the matter with its representatives in Congress. It will not do to let this most serious attack on the engineering profession pass by as a mere matter of departmental routine. The politician considers successful any move he can get away with. He banks on popular indifference. Let the engineering profession show that it can defend itself.

Robert W. Hunt

WITH the passing of Robert W. Hunt one of the few remaining pioneers of steelmaking departs. His early work fell in the period when scientific method struggled for recognition in the iron industry, and Captain Hunt did much to hasten that recognition. He will long be remembered, the world over, both for his years of practical activity in the mills, with their fruitful results in the development of working methods and machinery, and for his long, successful career in testing and inspection of mill production. But his memory rests even more securely on the rugged honesty and openness that seemed to mark him as a man among thousands. It is this characteristic which made Robert W. Hunt an inspiration and a force of influence. And surely this same characteristic of his mind was a chief factor in determining his progress and his achievements. The world needs men of his type.

Unified Railway Terminals

THE unification of terminals, or the operation of terminal facilities of different railways in the same city as a unit, for the public benefit, is a problem of recent growth which may assume wide importance, even apart from the problem of railway consolidation with which it is closely related. The concentration of passenger facilities at Portland, Ore., into one station instead of two stations, as described in this issue, is an example of what may be accomplished by co-operation between individual railways and between a group of railways and the city. With all service combined in one union station during war conditions, the advantages to the public were so evident that a proposal to revert to the original two-station plan aroused protest. Con-

ferences between the parties interested resulted in the adoption of a one-station plan which is beneficial to the railways, the city and the public. Freight terminals present a somewhat more complicated problem owing to their greater number and extent, in any one city, but probably there are cases where concentration and co-operation may be applied with mutual benefit, even without complete unification. It is true that in some places, notably in the few very large cities, complete unification is undesirable as tending toward a traffic congestion which latter day municipal planning is trying to avoid, but study of the possibilities of terminal amalgamation would be worth while in most of the cities under a half-million.

To Open Up Alaska

THE visit of the President and some of his cabinet to Alaska doubtless has for its primary purpose the education of those officials, but it should also be quite as important in focusing attention on that much abused peninsula. Newspaper men accompanying the party will see to it that the people all over the country are informed as to the chaotic condition of control in Alaska and the gradually decreasing productivity of a potentially rich territory. Jurisdiction over Alaska is divided among 35 different departments and bureaus of the federal government, most of which center in Washington. A greater measure of self government and of home rule is imperative but what is more necessary is a revision of the excessive application of the theory of conservation which has successfully throttled development. There is need for Congress to reconsider the principles of conservation laid down in the Roosevelt administration, as they apply to Alaska, and to permit judicious private exploitation. Alaska too long has been thought of merely as a source of mineral wealth. It has vast possibilities in other natural resources, notably in timber and pulpwood, and they should be unlocked. The Presidential trip should result in some useful activity in the coming Congress.

Building Accidents Analyzed

AN EXCELLENT piece of analysis has been done by the committee of the New York Am. Soc. C. E. section in its report on the general subject of building accidents reprinted in this issue. Such accidents are sporadic, and they always bring in their train upheavals of public opinion demanding some reform in the condition that caused them. Interest in such reform, however, as a rule soon dies out and conditions remain about as they were before, that is to say, responsibility for safety continues to be left in the hands of an inadequately manned building department, which when accidents do occur can generally be shown to have had very little to do with the failure. The committee's report is an analysis of the causes of building acci-

dents, and a plea for reform of professional organization and attitude, which, it is hoped, will tend to the lessening of such accidents. Specific recommendations toward this end are given, but they reduce to one main idea, that is, that responsibility for the safety of buildings must be centralized on some individual in each building. The committee evidently feels that it is hopeless to expect that law or governmental supervision can insure safe construction. They do feel apparently that a method of licensing might be developed whereby it could be insured that a competent technical direction will be legally insisted upon in every building. Methods whereby such centralized responsibility may be brought about are set forth in the report, which could well be made the subject of study by every local engineering society in the country, with a view to activity in this same direction in each of our large cities. There is plenty of knowledge of how to build safely. The difficulty is in seeing to it that those who do not have that knowledge are kept out of the building business.

Bridging the Golden Gate

DREAMERS have often talked about bridging the mile-wide entrance to San Francisco Bay, the Golden Gate. Occasionally, too, the talk has taken a turn that gave it some measure of popular attention. But never before the present discussion of the subject has the subject been within the range of practical planning and serious business consideration. There is now in existence a very evident purpose on the part of San Francisco to overcome the great handicap of its separation from the counties to the north, and a Golden Gate bridge is no longer the distant dream that it has been at all times in the past.

For a number of reasons, it has never been difficult to draw attention to the idea of such a bridge. The Marin County hills to the north would become a great suburban residential district, with corresponding increase in the value of property there. The West Coast metropolis would gain a direct highway outlet to the northern counties, connecting large sections of country that now have communication over long circuitous routes and giving the densely populated tip of the San Francisco peninsula access to the regions north and northeast—an urgently felt need in these days of dense automobile traffic. Last year something like 74,000 motor vehicles were registered from the 46 square miles of the San Francisco peninsula, which now must travel to and from the city by way of a single route to the south.

The great cost of the bridge project, together with its formidable engineering difficulties, has hitherto stood in the way of its serious consideration. A fear that there might be opposition to a Golden Gate bridge on the part of the War Department has no doubt also been of influence, though so far as known there is no tangible foundation for such a fear. Since the bridge would connect two counties its financing by public funds would present the usual difficulties of inter-county construction, but enormously magnified by the size of the project and the disparity in conditions of the two counties. And as to private financing, the certainty of adequate return on the great cost was lacking.

The inter-county difficulty has largely been swept aside, and the problem of financing thereby largely simplified, by the passage of an enabling act by the

recent California Legislature, which authorizes counties to form a bridge and highway district with power to levy assessments and issue bonds for the work they may desire to carry out in co-operation. A committee has already been formed to proceed under this act. The city engineer of San Francisco has drawn public attention to a plan for a 4,000-ft. span across the Golden Gate which it is claimed would cost only \$25,000,000. Two other schemes, using a location somewhat inside the Gate and more nearly in the natural line of traffic, would provide even cheaper crossings, and do so by more approved methods, though following a somewhat longer water route. Thus, the elimination of the difficulty of private financing seems to have brought the scheme within the range of practicability at once, and in so doing has served to give new expression to the traffic demands which are ready to support the project.

Thus, another of the country's great bridge crossing problems that remain to be solved is brought into view as an early possibility. The engineering difficulties which it presents are of great magnitude, yet the present resources of the art make them less serious than those of financing. Now that the legislature has made it possible to underwrite a publicly owned bridge, the project is within measurable distance of attainment. Its actual execution, it would seem, awaits only upon the definite determination of the people of San Francisco.

Motor Taxes Are Building the Roads

DESPITE all the arguments of all the automobile-association tax experts the people are assessing the cost of highway improvement on motor-vehicle users. It seems a curious situation. Apparently the car and truck owner, who, as an association member, subscribes to its contention for reduced taxes and their use only for maintenance is, as a citizen, ready to assume increased taxes and to approve their use for original construction when it is a matter of bettering his own traveling conditions. The philosophy of the situation matters little, however, in the face of the facts. These are that over the country the policy is confirmed of raising funds for roads by taxing motor vehicles and the fuel which they consume. A number of states indeed are talking of a tax on tires.

Vehicle taxation for road upkeep is an old practice and ever since they began to be required automobile license fees have been appropriated to road work. Always, however, a general property tax has been considered a main factor in providing money for highways. There is plain indication that the situation in respect to the general tax is approaching a change.

In Wisconsin, for the first time in a purposeful way, motor vehicle users are being taxed not to raise funds primarily for increased road improvements but to relieve present property taxes from a large part of the burden of highway building and upkeep. The new gasoline tax and the new license rates increase by \$4,000,000 the taxes which automobile and truck owners must pay. As a result general property taxes will contribute \$4,000,000 less toward road construction and maintenance. This is extension of motor-vehicle taxation well in advance of anything undertaken elsewhere but exactly the same trend of thought is being exhibited all down the line of road building states.

In the seven states of the middle south, the Caro-

linas, the two Virginias, Tennessee, Kentucky and Missouri, it is planned to finance an aggregate of \$400,000,000 in bonds by motor licenses and gasoline taxes. Not a penny increase in property tax will be asked to pay the interest on and amortize this enormous debt. Texas in recent legislation has doubled the taxes imposed on motor-vehicle users. Indeed in every state but one which last winter took any action on license fees there was an increase in rates.

While there is developing a general increase in motor vehicle license fees, a clearer indication of popular thinking, that the cost of road improvement is the debt of those who operate motor vehicles, is exhibited by gasoline tax legislation. The number of states imposing taxes on gasoline has doubled in the last six months. Recent legislation has, however, shown a strong tendency to impose higher rates. As has been stated, a tire tax, in addition to the gasoline tax, can be foreseen as a possibility.

It requires no further statement of fact to demonstrate that the motor vehicle is being taxed and that it will continue to be taxed and probably the tax rates will be increased instead of reduced. The United States as a whole has embraced the policy of making the motor vehicle user pay for the roads which he uses. And the motor vehicle user is showing astonishing willingness to assume the debt. Indeed there is no longer much force in the railway argument that they are being taxed to build up a rival transportation system which pays no taxes.

Progress in Rapid Transit

UNDER the pressure of growing necessity a number of our largest cities are again taking up actively the development of plans for better city transit. Looking aside from Philadelphia, where one element of the trunk-line subway project developed six or seven years ago is now being put under contract, we find that serious thinking ahead is being done at New York, Detroit and Chicago. Reports made public within the past week in two of these cities show, moreover, that the thinking is independent and energetic. The situation for real progress in rapid-transit development is more hopeful than at any time for a dozen years past.

Of the many ideas embodied in the Chicago report of the local transportation committees of the common council, peculiar interest attaches to that of making elevated railways the chief component of the comprehensive plan. The completed rapid-transit network as projected is to be seven-eighths elevated railway and only one-eighth subway; of the new lines in the network, four-fifths are elevated and only one-fifth subway. This is in striking contrast to what is found in all other rapid-transit planning of recent years, where subways were the principal ingredient.

Elevated railways are cheap, while subways are costly. But a strong prejudice against elevated railways is prevalent, due largely, we believe, to the many offensive features of the noisy, open-floor structures of New York and Chicago. Because of this prejudice the possibilities of better elevated-railway construction have been ignored, with the result that rapid-transit planners have found it expedient to bow to the demand for subways. It was inevitable that the systems so planned would prove enormously costly and that a network of lines extensive enough to carry rapid transit

to all corners of an area like Chicago would prove to be a financial chimera. When elevated railways are restored to a more important position in the scheme of rapid-transit affairs, rapid-transit progress will be brought measurably nearer.

A definite aim to distribute instead of concentrate traffic is another feature of the Chicago plan which brings to the front a new idea—new in the sense that though recognized in the past academically, as a very desirable thing, it has rarely found concrete representation in a rapid-transit project. But this and other points of the report which the interested reader will notice may be passed over in the present comment, in favor of another matter discussed in both the New York and Chicago reports, which promises to have great importance, possibly in the very early future. This matter is the relation of the suburban or commuting traffic of the steam railroads to the city transit.

Nowhere has it been possible to extend the municipal rapid transit system far enough to tap the suburbs and take over the commutation traffic developed by the railroad lines. Nor will it ever be possible to do so. The railroads will continue to build up suburban population along their lines and must serve as the twice-daily means of transportation for this population. There follows inevitably a concentration of traffic at the city terminals of the railroads which increases in seriousness as the city grows and which ultimately leads to conditions, in Chicago and New York for instance, that are excessively burdensome and tend to disorganize the whole transportation system of the city.

To remedy this situation a radical cure must be applied. If the railroads are to continue to carry the commuting traffic, and if the concentration of this traffic at single terminals within the city is to be avoided, one of two things must be done. Either the railroads must be extended as rapid-transit lines within the city limits or the suburban traffic must be transferred to the city transit lines at outlying points and distributed by those lines. Local conditions will determine which plan should be used. For Chicago, where the suburban traffic problem is not acute, the report recommends the latter plan as an ultimate goal, to be attained when the excess capacity of the city transit system is sufficient to handle all or part of the suburban traffic. For New York, where the problem is one of immediate urgency, the report considers that as the city transit system is already overloaded with no prospect of growth greater than the increase in the city's demands upon it, the steam railroads should extend their suburban lines to new stations in lower Manhattan.

The problem and its solution are equally obvious. But hitherto the pressure of purely intramural transportation problems has been paramount in virtually every community that has had to deal with rapid transit. Consequently the suburban commuting problem has been ignored, with the rather undesirable result of increasing greatly the concentration of housing within city areas, to the disadvantage of the open and healthful suburban areas. Future development of rapid-transit thinking will, we believe, follow a rather different course. It may even go so far, in some instances, as to make the co-ordination of transit and railroad transportation the controlling element of planning. The emphasis given to the problem by the two present reports assures early progress toward more comprehensive rapid-transit planning.

Building Accidents and Their Prevention

Report of a Committee on Structural Safety in Building, Presented to the New York Section of the American Society of Civil Engineers

After the disastrous collapse of the Knickerbocker Theater in Washington, D. C., on Jan. 28, 1922, which followed only a few weeks after the failure of an uncompleted moving picture theater in Brooklyn, the subject of building failures and how they may be prevented in future was discussed by the New York Section of the American Society of Civil Engineers. At the meeting of Oct. 18, last, several methods tending to improve the safety of buildings proposed by members were referred to a committee, which was charged with a general study of the subject of structural safety in building.

This committee, composed of William Cullen Morris, Daniel L. Turner, and F. E. Schmitt, presented a report at the meeting of May 16, most of which is reproduced here.

A thoroughgoing change in present building methods is recommended as the best means of improving present unsatisfactory building conditions. The entire study and the recommendations are limited to building operations of technical character, and do not apply to such simple building work as may be carried out safely by craftsmen without technical direction.

MANY practices in the conduct of building are unsound and unsafe. This condition affects seriously the professional work of engineers as well as the security of the public. Its fundamental cause lies in the fact that incompetent persons are allowed to build, and do build. While this evil is deeply rooted in existing customs, its complete elimination is necessary to place building on a sound basis.

Effective reform rests on practical application of the view that building is a specialized technical activity involving a distinct hazard. In accordance with this view, building should be restricted to persons possessing the knowledge and skill required for carrying it on properly, namely architects and structural engineers. Combining competence, responsibility and authority in one person will effectively guard safety. The proper operation of this system of procedure should, of course, be protected by administrative control by the public building authorities, as a means of enforcement and as a check on full discharge of responsibility. Further, in view of the special position of professional men under the system indicated, co-operation by professional organizations in supervision of its working will be of value.

The subject of safe building is peculiar to no one city but is of nationwide concern and constitutes a single problem. It involves the engineering and architectural professions, the contracting industry, and civic and property interests. If effective reform is to be attained, representatives of all these groups should work together in shaping it and bringing about its adoption. Such a co-operative body should be so constituted, moreover, as to have broad geographical scope and influence. The committee recommends:

I—That the Board of Direction of the New York Section develop a plan for assembling a broadly representative body to devise and promote the adoption of a plan for eliminating unfit persons from direction of building as proposed by restricting it to architects and structural engineers and the practical definition of competence by state licensing; and that the Board initiate the organization of such a body through the Society.

II—That in order to oppose the practise of designing by code and to emphasize the necessity of applying independent technical judgment in design, the Section be asked to express itself in favor of defining a building code as a minimum and to promote the adoption of such definition by statute.

III—That consideration be given to the possibility of establishing continuous professional action on structural engineering matters and on building accidents, with a view to assuring the maintenance of sound conditions within the profession in connection with building, assisting public building administration, and providing for the prompt detection and correction of faults in established technical practices in building.

IV—That, since the architectural attitude toward the responsibilities involved in building affects the corresponding engineering attitude, the Board endeavor to bring about joint consideration of these responsibilities with representatives of the architectural profession.

V—That the special problem of assuring and maintaining the safety of existing buildings, which was not covered by the present committee's work but which appears important, be made the subject of a separate inquiry.

General Building Conditions—Building failures occur under quite varied circumstances. As all such circumstances bear on the value of reform measures or safeguards, the committee sought information on building conditions and examined some 40 failures covering a period of more than 20 years. Of these 40, only two or three can be classed as unpreventable.

In general, the facts establish that building failures are not chargeable to insufficiency of existing technical knowledge, and that the problem of assuring safe building is organizational rather than technical. Safe design and construction methods are known to men skilled in the art, but the actual conduct of building does not always assure that such methods will be used or such men be in control of the work—even in apparently normal practice, as in the Knickerbocker Theater case and some others. Common faults in the direction of building work are: Ignorance of what good building requires, a belief that building codes guarantee safety with ample margin for neglect or variation, dependence on the city building department, neglect of duty, confusion as to where responsibility lies or even absence of responsibility for some part of the work, and often plain cupidity. Technical men are sometimes involved, through incompetence or neglect of duty. It is stated by building officials that sharp practice in taking advantage of inevitable shortcomings of the building law is a factor in unsound building, and that deliberate evasion of the law and even substitution of fraudulent plans for approved plans are known.

Briefly characterizing present conditions of building control, it may be stated that it is possible for a man with no knowledge of building to present plans for a building, to obtain a permit for erecting it, to employ craftsmen, subcontractors or a general contractor of any character, to create public dangers subject only to the objections of a building inspector should such a man chance to become aware of the condition, and finally to put the structure to public use. He may engage an architect or an engineer and may dismiss him at any time—even at a stage when competent supervision is vital—and may direct the work himself. Or, he may in good faith engage as architect or engineer a man who is incompetent, who sells material or who solicits employment on the claim that he can save a few tons of steel over another designer or have a thinner wall

approved by the department, or who is satisfied to represent an important truss by a rough diagram, trusting that proper construction will somehow be obtained.

Remedial Proposals—Several building reform proposals were advanced at the Section meeting of Oct. 18, 1922. The three principal ones are: (a) that of J. B. French, requiring that a structural engineer certify to the safety of any building of public assembly before it is opened to use; (b) that of R. P. Miller, restricting building permits to responsible persons registered with the city building department; and (c) that of L. D. Rights, making the owner legally liable in case he fails to employ a competent architect, engineer and superintendent.

The Miller and French proposals if applied effectively would have been of value under the conditions of some of the recorded failures. In many other failures, however, they would not have made the work safe; additional changes in building methods and control would have been required. The Miller plan, a direct attempt to eliminate unfit persons from direction of building, approaches closely to effective cure of the existing evils but its weakness in failing to provide technically competent conduct of work is vital. Basing the grant of a permit on "responsibility" in place of competence is believed to be open to decisive objections. Yet the plan has the great merit of being the readiest and simplest of the remedies for building evils so far proposed. The committee believes that, however modified, it should include the French plan, which is a necessary element in building reform.

The third proposal, to hold the owner liable for employment of competent men to plan and erect this building, has a fundamentally important purpose. Its practical value depends on the means used to bring about the specified result. No such means have been suggested. The owner's financial liability for damages resulting from failure of his structure, which exists under the common law, is not a sufficiently powerful motive, as past failures demonstrate, and any attempt to attach criminal liability to the owner is believed to be questionable in both its legal and its practical aspects. The principle that safety requires that building work be planned and directed by competent men is not likely to be applied much more effectively than at present so long as the owner is left free to choose. If the principle is valid it is a proper subject for mandatory legislation. The owner's interest will in any event supplement the architect's or engineer's responsibility, since both parties would be subject to penalty. But the primary authority and responsibility for the work must be placed definitely in the hands of the technical man. Any uncertainty on this point will merely perpetuate the present causes of building failures.

Other proposals for guarding against unsafe building, advanced on earlier occasions by various investigating bodies, were also examined by the committee. It appeared that most of them were the response to one particular failure or one set of faulty conditions, and would fail under other conditions. A general proposal to bond every building operation, with evident expectation that the surety would guard the safety of the work, is not believed to be either effective or practically acceptable. Three important proposals are those contained in the report of the Brady-Eidlitz-Just board¹ in 1905, and those made in 1922 by expert committees of the Associated General Contractors and the Washington chapter of the American Association of Engineers² after investigating the Knickerbocker theater collapse. Most of their individual recommendations are necessary parts of an adequate system of building reform; the first-mentioned report is particularly noteworthy.

Technical Direction by Public Agency—All thoughtful discussion of building safety has recognized that competent technical direction is the necessary fundamental. Many believe however, that this can be obtained only by governmental agency; in other words, that there is no hope for better building except through more complete plan examination and field inspection by the public department. Even the likelihood that such development would reduce the engineer's and architect's functioning to minor rank does not appear to discourage these opinions. The committee

is convinced that improvement does not lie in this direction, and that on the contrary the public supervisory functioning should be adjusted to the purpose of assuring efficient and dependable functioning of the private parties to a building operation. It may be remarked that if full technical guidance of building were to be supplied by the city building department, the cost of carrying it on would be multiplied ten to thirty times, and a quite unmanageable administrative machine would be created.

Provisions for Effective Technical Control—Responsible technical direction of building work with full authority is provided at present in building operations of the higher grade on the initiative of the owner himself, who retains an architect or engineer and leaves this technical man free to work out the problem with full responsibility until ultimate completion and even beyond. Where the system is applied in full, it is entirely effective. The combination of technical competence with complete authority over the work and responsibility for the result represents the basic essential of sound and therefore safe building practice. In the lower class of building work, and especially in speculative building, this system is more or less completely disregarded. The elimination of unsafe building conditions may be brought about by compelling the application to this class of building of the same sound system of building direction that is adopted in high-class building work as a matter of course. While it is true that the owner's interest would even now be served by the adoption of the same system in his work, whatever the kind or grade of building to be constructed, this advantage is not powerful enough to overcome his willingness to gamble against the chance of mishap for the sake of a cheaper result. Legal institution of the system must therefore be resorted to. The method of doing this should, for practical reasons, take account of the weaknesses of present building control.

A list of such weaknesses, compiled largely from the facts of actual failures, is given in the belief that it represents more or less completely the prevailing situation in most cities:

- (a) Unauthorized building may go on.
- (b) An incompetent or irresponsible person may apply for a permit to build.
- (c) The applicant does not undertake to conduct the work and does not assume responsibility for the result.
- (d) Plans may be drawn by an incompetent person, or by one not competent in some essential part of the work; plans drawn by a competent person may be changed by an incompetent one; neither designer nor user warrants the adequacy of the plans.
- (e) Where structural engineering enters into the plans, this part of the design may be furnished by others than the designer, including material men, without assumption of responsibility and without proper check on its adequacy.
- (f) A permit may issue to any one, regardless of competence, and frequently any one may build under the permit.
- (g) Permits are sometimes issued on incomplete plans, and even on unapproved plans.
- (h) The permit usually imposes no obligation beyond following the building law, and fails to make safe building a condition of the permit.
- (i) Competent technical direction of the work is not required.
- (j) Difficult engineering operations may be undertaken without engineering direction.
- (k) The technical authority is not final, and if the architect's or the engineer's authority on the work is overruled by less competent persons the building department is not concerned.
- (l) Inspection by the building department, weak as it is, constitutes the main protection against violation of building law or safe practice.
- (m) Control powers as represented by stop orders, suspension or revocation of permit, or special inspection charges, are not always provided or used.
- (n) Competent certification of completion in accordance

with the plans, the building law requirements and the demands of safe construction is not made a requirement.

Three of these defects in control, namely (a), (g), and (m), are mere administrative shortcomings, and require no essential change in building control; for example, both police co-operation and prominent placarding of building operations have been found effective in preventing unauthorized building. All the other defects, however, involve either a failure to demand that building be directed with competence, or failure to insist on proper discharge of the responsibility arising out of the work.

A system of technical control devised to meet the conditions indicated by these defects requires the following main provisions:

(A) The conduct of building work is to be limited to structural engineers and architects.

(a) Application for a permit must be made by an architect or a structural engineer. Permit is to be granted only to the applicant, is to be non-transferable, is to stipulate his continuous direction of the work, and is to authorize building only by the permit holder himself or by a registered builder.

(B) Architect and engineer are to be held responsible in design, detailed supervision and inspection of execution for safe conduct and completion of the building operation, and are to be placed in full authority over the work.

(b) Plans for a building must be prepared by an architect or a structural engineer and must bear his personal certification that he prepared the plans, that they conform to the law and that they are adequate for safety. The applicant must certify that he has checked the plans and accepts them as his own. Preferably he should be required to submit proof of the adequacy of the design in its main features, and on demand of the department also of any details.

(c) Application for the permit must include a specific undertaking to conduct the work and assume responsibility for its adequacy until completion. The permit must embody this undertaking.

(d) In all dealings with the work under the permit the department must recognize the permit holder as in charge to make his authority over the work fully effective.

(e) A certificate of completion, adequacy and conformity to plans and law must be rendered by the permit holder, the certificate to be filed of record with the plans.

(C) Engineering competence is to be provided for the design and construction of buildings or parts of buildings involving engineering elements.

(f, g, h, i) Provisions identical with (b) to (e) apply to engineering work, but should be established separately because past failures have shown that there is special danger in indefinite merging or overlap of architectural and engineering responsibility. Personal certification of design is here also essential, regardless of whether the designer is in independent practice, is employed professionally, or is a material man or contractor. Supervision and certification of completion are to follow.

(j) Special engineering work, as difficult shoring or underpinning, requires special direction, and the department must have power to demand such direction at any time.

(D) Means are to be provided for enforcing these requirements through the administrative procedure of the building department, with revocation of permit and assessment of costs on the property as measures of control.

(k) The efficiency of the building department must be increased in order to administer these measures. Its inspection staff should be raised to the architectural and engineering grade.

(l) Control must be improved by requiring the approved plans to be kept on the work, by specific

vesting of power in the department to require additional safety measures or special direction, by more careful safeguarding of changes of plan during construction, by use of stop orders, by provision for revocation of permit, and by provision for assessing the cost of all special control proceedings on the property as a lien.

(m) Power must be vested in the department to refuse plans or applications for permits from an architect or engineer who has made himself subject to revocation of a permit.

(n) Registration of builders with the department is desirable for more effective control.

(o) Registration of building supervisors for minor work is a desirable auxiliary.

(E) Competence of architects and structural engineers is to be established by a licensing system.

(F) Revocation of license for cause is to be provided for.

This outline is given not as presenting full working details but as indicating the essentials sufficiently for proper consideration of how building practice would function under mandatory technical control. The actual details should be framed by a body composed of representatives of the several parties concerned, after joint study of the subject. Such study could properly be extended to include a determination of the scope of building control, so as to decide what classes of structures not intended for occupancy affect public safety so directly as to require the same control as buildings.

Defining Competence—The necessary definition of what constitutes a structural engineer or an architect may be attained by state licensing. Licensing alone merely defines the technical man, and cannot materially improve building conditions unless provision is made for placing him in control of building work. The Illinois license and restriction laws for architects and structural engineers seem to be operating fairly well so far as they go; as they protect only design and fail to demand competence in direction of construction they can have only a limited effect.

Supervisors and Builders—Establishment of a separate grade of building supervisor is believed to be warranted only for the proper care of minor building work, and such operations as demolition. Work of definitely technical kind should be directed by the designer or by a man of equal grade who will accept the design on his personal checking and assumption of responsibility. Local registration of building supervisors with the building department is preferable to state licensing, and will facilitate closer check on their functioning. Registration of builders, proposed some years ago by R. P. Miller and endorsed by the Building Officials' Conference, is also considered desirable, less for eliminating incompetence than for strengthening the department's control over building practice by enabling it to place a penalty on the builder who works unsafely or in violation of law.

Professional Co-operation—Certain professional questions are connected with safe building. Since good building depends ultimately on the skill and integrity of engineers and architects, the attitude of the professions will influence the results obtained. When these professions further are established as solely competent to carry on building, the professional status is an even more important subject of consideration. The committee believes that the questions concerned merit careful study. It recommends that professional co-operation in bringing about and maintaining safe building conditions be considered, and suggests three elements of such co-operation: (a) Definition of the professional obligation incurred in engagements connected with building, and provision of means for combating incompetence and malpractice; (b) Formation of local groups or committees to maintain contact with building administration and its problems in the interest of sound building; (c) Provision for current study of building failures with a view to improving technical practices.

Existing Buildings—Representations have been made to the committee that the public confidence in the safety of theaters and halls has been sufficiently disturbed to war-

rant a general inquiry into their condition. While no widespread doubt of this kind is apparent, this fact in itself does not dispel the uncertainties arising from the collapse of the Knickerbocker theater. A general structural survey of theaters and halls by expert committees of professional engineering bodies acting in a disinterested way would constitute an important public service. Because of the magnitude of the undertaking, however, the committee is not prepared to recommend present action.

Quite apart from theaters, supervision of the safety of existing buildings is a matter of growing concern, particularly in regard to buildings of some age, to changed occupancy and to reconstruction. The collapse of the Stratford apartment house two or three years ago carried a warning of the possible instability of old buildings. Public building control faces many difficulties in assuring public safety with regard to existing structures, which rarely are in competent care. The committee believes that the subject should have consideration in any revision of building department functions. It also believes that a separate inquiry into the relation of existing buildings to public safety is desirable.

Appendices

Analysis of Building Failures—Analysis of numerous building failures with respect to the individuals at fault showed that each one of the typical parties to a building operation has been responsible for one or more failures, but owner and architect by far most frequently. Often no supervision was provided, and this is chargeable to the owner; the list of owners thus at fault includes responsible, well informed individuals and corporations. The entire history of failures as well as the experience of building officials reveals a widespread lack of appreciation, on the part of non-technical owners, of the essentials of safe procedure to assure proper technical results.

Where architectural supervision was provided, it was in some cases plainly superficial and ineffective, serving as a check on the contractor's bills rather than as a safety measure. This is charged against the architect as a fault. The same applies to cases in which the architect did not provide the necessary engineering skill for design and supervision of structural engineering phases of the work. Correction of these faults must be sought through definite assignment of responsibilities and through a clarification of the question of what constitutes adequate performance of a professional engagement.

A study of the part played by the separate functions or agencies which enter into building work led to the following conclusions: (1) Deficiencies in building codes cannot be charged with any material part in failures, though the complexity and great detail of codes has often been confusing and even misleading to a dangerous degree. (2) Bad designing has caused many failures, due variously to incompetence, negligence, failure to provide sufficient detail in the design, failure to engage an engineer for needed structural or foundation design, improper delegation of parts of the designing to material men and others who did not assume effective responsibility and whose designs were not checked. (3) Plan examination, while often inadequate, has not been directly responsible for any failures, though it has contributed to some. (4) Loose control of authorization to build is a marked source of danger in some cities and produced one recent failure. (5) The grant of building permits is not limited to persons competent to carry out a building enterprise. (6) The form of contract does not appear to be related to safety, as instanced by the fact that at least one failure occurred in a cost-plus contract. (7) The practice of the owner subcontracting direct is highly hazardous. (8) Bad work by the contractor is a minor though not negligible factor. (9) Supervision of building, though vital to safety, is almost always absent or is of superficial character in that class of building which is recognized by building officials as troublesome or dangerous and which has contributed many items of the failure record. (10) Municipal inspection is so inadequate as to afford little protection in case of faulty performance by the private parties.

More generally, it appeared that the organizational system and precautions applied in general construction work, and found to be adequately safe there, are frequently absent from building. The control by public building departments does not insist on their being provided, but dependence on that control appears to be one motive for not providing them. It is obvious that a system similar to that used in general construction would assure safe building, through its centralization of authority and responsibility in a technical competent person.

Differences of location and time were found to be unrelated to the results of these analyses, but all the data gathered, including the facts of the earlier failures, proved consistent in respect to underlying conditions. Building departments differ in excellence, and most of them have improved steadily, so that some cities now have substantially as good building administration as is to be expected under present functions and powers. On the other hand, building is growing more complex, and its demands on the ability and integrity of technical men are increasing. This development appears to be proceeding more rapidly than the gradual improvement of practice, especially in view of the spread of difficult and hazardous building to smaller communities, where the protection of public safety in building is least efficient. All things considered, the problem of structural safety appears to be growing more critical, rather than the opposite.

The Building Department—Proper organization of work in the degree found necessary in other construction is commonly thought unnecessary in building, partly because the work is looked upon as non-technical and simple, but partly because of the dependence placed in the municipal building department for ultimate safety. This dependence is apparent in the attitude of press and public toward building questions, and even in that of many technical men. It involves a belief that engineers, architects and builders are fallible but the building department's plan examination and field inspection protect or ought to protect the public. Unfortunately, also, the daily work of building officials shows much fallibility, negligence and incompetence, and violation of law, on the part of persons who propose to build. The official of one large city states that every set of building plans submitted to his office requires to be changed before it can be approved.

Dependence on the building department for safety is not warranted by the facts. Further, the function of the department, a policing function, is to inspect rather than supervise and direct building work. When the parties who engage in building rely on the department to assure safety, their own sense of responsibility largely disappears, and it is found especially in purely speculative operations that the municipal plan examination and inspection reduce by as much or more the care and conscientious effort of the designer as well as of those who should provide direction and supervision of the work. It enables these private parties to transfer some of their work and duty to the department, and the opportunity is extensively taken. The Knickerbocker theater collapse was a consequence of improperly guarded transfer of responsibility by the designer to other parties with final dependence on the building department. Any method proposed for improving building practice which does not furnish a fundamental corrective for this condition is certain to prove a disappointment.

Most building departments are heavily overburdened, and operate in reasonably satisfactory way only by virtue of hard work on the part of overtaxed and underpaid examiners. There is some evidence that this condition is becoming more serious. Plan examination is superficial at best, often being done by a process of sampling. In smaller places cases are known where the building official is not competent to pass on plans for other than the most simple building work, and approves them without examination. Field inspection as now conducted is in some degree a check on conformity to the law, but it cannot be regarded as an important assurance of safety. In short, building departments do not fully examine plans and do not fully inspect. To do even their present work properly, however, they are in urgent need of improvement both in quality and in size

of office and field staff. Vastly greater improvement would be required to fit them for carrying the full responsibility of safeguarding building, were this result at all practicable.

The building department should not assume any part of the duty to provide technical knowledge and skill to the building operation. This duty clearly rests on those persons who engage in the operation, and the department should confine itself to its obvious charge of enforcing and supervising the responsibility of the builders.

Building Codes—Building codes, commonly held to be important instruments of safety, appear to have been developed to a degree of elaborateness of detail which operates to the detriment of safety in some instances. They are usually specifications that attempt to cover all elements of building construction. Many designers use them as their sole guide. "Building code designing" has become a byword, and its effects appear in a number of past failures.

Complete specifying of sound practice is impossible in the field of building as it is in other fields of construction; yet the view prevails even among architects and engineers to some extent that any design which can be interpreted as complying with the building code is safe, relieving them as designers from further responsibility. It seems desirable to emphasize the danger of this view by defining the code as a set of minimum, not necessarily sufficient, requirements, and by charging the designer with responsibility for safe designing regardless of the minimum fixed by the code. The department then should have discretionary power to reject plans and to stop work even though conforming to the code and the plans. Its work would be assisted if designers were required to present affirmative proof of the sufficiency of their plans, rather than that the department should bear the burden of disproof.

The detailed codes now current are known to be burdensome to the capable and conscientious designer while at the same time they are not adequate to prevent bad design. Simplification of codes therefore is a desirable improvement. However, it is by no means as vital to building safety as the revision of building control, and for the present purpose may be disregarded as secondary.

Uniformity of codes has been much discussed, apparently in the belief that it is both a safety and an economy measure. The present study has not indicated any relation between the safety of building work and uniformity or variation of codes. It seems likely that uniform codes would have some advantage in the way of convenience to users; they are not believed to promote safety.

Professional Relation To Building Safety—(a) Many building failures have brought to light undesirable professional conditions. Professional incompetence has repeatedly been recorded. In other cases, sometimes perhaps under the pressure of low fees or excessive expense, there has been obvious neglect of part of the professional man's duty to assure safe completion of a piece of work that he has entered upon, as by failure to give supervision in the field, or by inadequate supervision.

No standard appears to exist by which the professional duty assumed in any case may be determined. Commonly the terms of employment are considered to limit the obligation, so that a designer frequently sells plans, or inspects the execution of his design only superficially. While legislative defining of responsibilities would tend to clarify the situation, it is desirable that professional standards be superior rather than inferior to the law's requirements.

(b) The public and the profession have a joint interest in protecting the system of public building administration from the various harmful influences that work against its efficiency. Professional co-operation with the building department would be of distinct service in combating the exercise of political pressure to weaken the forcefulness and impartiality of building law administration, the grant of violation permits by city councils, ordinary deterioration of the department, the effects of obsolescence of the code, and other causes of unsatisfactory building conditions.

(c) Some building failures have revealed imperfections in technical knowledge of building work, or in current technical practice, which have had to wait for their removal on

the slow process of amending the building laws or else on spontaneous general change of practice. The prohibition of cast-iron column construction for high buildings and the elimination of faulty practice in reinforced concrete, for example, came about slowly in the absence of professional action on a series of failures. Service to the community obligates the profession to undertake on its own initiative the prompt study of points of imperfection revealed by structural accidents. As a prerequisite to such study the technical facts of failures need to be determined by current investigation of failures as they occur.

It is believed that means for dealing with these questions continuously should be provided by professional action.

¹Abstracted in *Engineering News-Record* of March 30, 1922, p. 532.

²After a series of flat-house failures in New York City in March, 1905, a board consisting of Thomas J. Brady, Otto M. Gillitz and George A. Just recommended to the borough president of Manhattan, New York City, that (a) architects be required by law to supervise the construction of buildings for which they furnish plans; (b) the competence of architects be assured by some system of license or registration; (c) permits be issued only to persons so registered; (d) mason and structural contractors be licensed; (e) work by persons not licensed be declared unlawful. These recommendations were reproduced in *Engineering News* of April 13, 1905, p. 391.

Suggestions for Engine Terminal Improvement

DESIGN of locomotive terminals was treated from three different points of view at a meeting of the Western Society of Engineers recently. R. N. Begien, then general manager of the Baltimore & Ohio R.R., discussing the operating requirements, laid stress on the economies resulting from greater service and fewer locomotives when there is rapid handling of the engines in cleaning fires and taking coal and water so as to make ready promptly for another trip. For the design of an efficient terminal, knowledge of operating conditions and terminal work is an essential supplement to engineering knowledge. The mechanical and engineering requirements were discussed by L. K. Silcox, general superintendent of motive power of the Chicago, Milwaukee & St. Paul Ry., and W. T. Krausch, engineer of buildings, Chicago, Burlington & Quincy Ry.

Mr. Silcox analyzed the time consumed in "turning" an engine, that is, in making an inbound engine ready for an outbound trip. This time averages $11\frac{1}{2}$ hr., but detentions increase the delay to 16 hr., so that a locomotive averages only 8 hr. of service per 24 hr. Increase of this period may be obtained by wider and better spacing of terminals in order to give longer runs, or by improving the facilities for handling the engines at terminals. He emphasized the fact that increase in capacity and equipment of roundhouses has not kept pace with the increase in number and size of locomotives to be served. As an instance of the economic aspect, he explained that if the average frequency of turning could be reduced to 1.3 times per day instead of 1.4 times, as at present, with a reduction of 50c. in cost of terminal service per engine turned, the annual saving on 2,000 locomotives would be about \$650,000, which at 10 per cent for interest and fixed charges would support an investment of \$6,500,000.

On the engineering requirements, Mr. Krausch said that in many cases an existing terminal can be so improved at moderate cost as to increase greatly the efficiency and economy of its work. In other cases it is economy to plan new terminals on new sites. He emphasized particularly that the only way to get improvement in operating results is for the engineering, mechanical and transportation department to: "Get together, stay together and pull together."

Experiments in Water Coagulation with Aluminum Sulphate

Relation of Hydrogen-ion Concentration to Precipitation and Dissolution of Aluminum Hydroxide

BY F. E. DANIELS

Assistant Engineer, Chief Chemical Laboratory, Engineering Division, Pennsylvania Department of Health, Harrisburg, Pa.

HILDEBRAND, BLUM¹ and others have made studies of the precipitation of aluminum hydroxide using the hydrogen electrode to measure the reactions involved. Buswell and Greenfield² and Buswell and Edwards³ have studied the precipitation of aluminum hydroxide on a filter-plant scale, and give data showing that its precipitation and resolution depend, in a large measure, upon the hydrogen-ion concentration. Studies made by the Virginia State Board of Health also show that this is true, but that the conditions for optimum precipitation depend upon the organic content of the waters and other available factors.

The purpose of this paper is to give experimental data showing the influence of the hydrogen-ion concentration alone upon the precipitation and dissolution of aluminum hydroxide, using a dilution and temperature comparable with those found in a filter plant. A dilute solution of aluminum sulphate was precipitated, (1) with varying amounts of sodium carbonate and (2) with varying amounts of calcium hydroxide. Hydrogen-ion concentrations were determined colorimetrically in the solutions containing the precipitates. Color standards were prepared using buffer solutions whose strengths were determined by electrometric titrations. The precipitates were filtered, ignited and weighed as Al_2O_3 .

The table accompanying this article gives the amounts of aluminum as aluminum oxide precipitated from 500-cc. solutions of aluminum sulphate. Curves were

the maximum amount of hydroxide was still precipitated with $Ca(OH)_2$. Anything more alkaline than this, however, caused the soluble calcium aluminates to form.

It is of interest to note that with either curve the inflection points showing the beginning of dissolution occur before a hydrogen-ion concentration of 8.3 is reached. At this point phenolphthalein changes from colorless to pink. It is occasionally the practice in filter plant operation to control the precipitation by means of this indicator. From the figures published in this article it is quite evident that a pink color with phenolphthalein shows that the water is alkaline enough to dissolve part of the aluminum hydroxide, and more so in the case of sodium carbonate than when lime is used.

Brom-thymol-blue begins to change from yellow to blue at a hydrogen-ion concentration of 6.0. As the

RELATION OF H-ION CONCENTRATION TO PRECIPITATION AND DISSOLUTION OF ALUMINUM HYDROXIDE

number of hydroxyl ions increases, formation of the blue color begins and gives a series of shades of green as the blue becomes more and more predominant. The dye is blue at a pH of 7.0 but intermediate tints of blue can be recognized until 7.6 is reached and the dye is completely blue; and then no further addition of alkali can change this color. By adjusting the alkalinity of the water until a tint of green color is reached with this indicator, it is possible to obtain the optimum zone for the precipitation of aluminum hydroxide. This results in economies in filter plant operation, in a water free from soluble aluminates and in a reduction of the corrosion of pipes.

Although the curves show that the residual reaction of the effluent should be on the acid side of neutrality to obtain the maximum precipitation of alum, there is an important reason why the filtrate should be alkaline. A bicarbonate alkalinity having a pH in the neighborhood of 8 or 9 is very much less corrosive than a more acid water, as the excess bicarbonate acts as a buffer and prevents the CO_2 from attacking iron. If it is desired to secure a water of such alkalinity, it should be secured by adding lime or soda after filtration, as has been done recently in Baltimore (*Engineering and Contracting*, Aug. 9, 1922).

The author wishes to acknowledge and give credit to Edward Martin, M.D., C. A. Emerson, Jr., and W. L. Long, who, at the time the above work was done, were respectively commissioner, chief engineer and chief chemist of the Pennsylvania Department of Health.

plotted giving the hydrogen-ion concentrations as ordinates and the parts per million of Al_2O_3 precipitated as abscissas. Using aluminum sulphate and sodium carbonate, the maximum precipitation occurred within the zone whose limits of hydrogen-ion concentrations were approximately from pH 6 to pH 7. In solutions more alkaline than pH 6.8, dissolution of the hydroxide as the aluminate began and continued with increasing alkalinity until the entire floc was redissolved at a pH of 10.5.

As the calcium aluminates are less soluble than the sodium aluminates, dissolution of the precipitate formed from calcium hydroxide did not begin as soon as the dissolution of the hydroxide formed from sodium carbonate. At a hydrogen-ion concentration of about 7.3

Passenger Terminal Improvements at Portland, Ore.

To Secure Joint Terminal City Vacates Streets and Railways Give Land for Widening Streets—Terms of Agreement

CONSOLIDATION of all railway passenger business in one union station at Portland, Ore., and the abandonment of a second terminal station, has necessitated not only material alterations and improvements in the railway terminal facilities but also extended negotiations with the city in regard to vacation of streets for railway purposes and the donation of certain railway property to the city. The general situation is explained by the plan, Fig. 1.

The principal passenger terminal is the union station at Broadway and Hoyt Sts., built in 1894 by the Northern Pacific Terminal Co., which is owned jointly

Revision of Terminals—A serious obstacle to expansion of the union station trackage was the existence of the Terminal Co.'s freight yard and engine terminal alongside the passenger tracks. After the study of the situation it was decided to provide a new freight yard and engine terminal outside the city and about two miles northwest of the union station. The first unit of this new freight terminal, known as the Guild's Lake yard, was completed in 1922, a large amount of filling being pumped in from the river by hydraulic dredges to form the site. With the ground at the passenger station thus cleared it was possible to provide at once two additional passenger tracks with a 19-ft. platform 1,600 ft. long. The remaining space was utilized for a local freight yard having team tracks, automobile loading platform, track scale and a crane for handling heavy freight. There is room also for another platform and two more passenger tracks when required.

In addition to team track purposes, this yard is used

freighthouse of Northern Pacific Ry. G, freighthouse of Southern Pacific Ry. H and J, freighthouses of S. P. & S. Ry. K, old passenger station of S. P. & S. Ry. Improvements in freighthouse facilities are to be made in 1924.

by the Northern Pacific Ry., Southern Pacific Ry. and Oregon-Washington Railroad & Navigation Co. In 1906, the Spokane, Portland & Seattle Ry. built a smaller station at Eleventh and Hoyt Sts., and this was used also by the Great Northern Ry. During the period of federal administration of the railways the two latter lines were diverted to the union station, but when the railways were returned to private ownership the Northern Pacific Terminal Co. notified these new tenant lines that it would be unable to accommodate them.

This proposed separation of railway terminals led to protest on the part of the city and various civic organizations, coupled with a demand for more adequate facilities, on the ground that public convenience would best be served by a single but larger terminal station. As a result, a joint study of general improvement of both the passenger and the freight terminals was undertaken in 1920 by the several railways.

for receiving and delivering transfers of the three railways owning the Northern Pacific Terminal Co. This latter company does not move cars to and from the yards of the trunk lines, but it does handle all switching business for tenant lines and has joint use of a double-track line between the passenger and local freight terminal and the new outlying Guild's Lake yard.

At present all the lines are using the union station and the traffic averages 48 inbound and 48 outbound scheduled trains daily, about twenty of these being local electric trains of the Southern Pacific Ry. to and from Willamette Valley points.

As now enlarged the station has four 19-ft. platforms 1,100 to 1,330 ft. long, connected by a 60-ft. transverse concourse opposite the headhouse, as shown in Fig. 2. Umbrella roofs cover the platforms for lengths of 150 to 300 ft. and over the concourse is a high shed roof. These platforms serve nine through tracks and four stub

tracks, the latter being for baggage, express and private cars. Provision is made for a fifth covered platform and two additional tracks, replacing three of the present freight tracks. Entrance to the station is to be improved and the block opposite the headhouse will be developed for parking purposes and as part of an attractive approach. A new station building will be erected eventually. During 1923 there will be expended about \$150,000 in track changes, street improvements and other work involved in the recent agreement between the Terminal Co. and the city.

Extensive improvements in freighthouse facilities and the local freight yard adjacent to the passenger station are contemplated, but these plans are not yet completed. Coach cleaning and storage tracks are now arranged along 9th St. north of Hoyt St. (see Fig. 1), but the second unit of the outside freight yard at Guild's Lake will provide a new location for these facilities, the space then vacated being utilized for freighthouse purposes. It is expected that this second unit will be built in 1924.

Viaducts and Street Widening—Since streets and railway tracks are at the same level, both street and railway

blocks. With city ownership of strips of land designated as "streets" extending across railway property, the railways have been at a disadvantage in developing their property, although they owned most of the land in the "blocks." Negotiations with the city authorities were started, therefore, in order to secure the vacation of these obstructive "streets" as an offset to public benefits resulting from improvements made by the railways.

For many years Portland has had a restriction in its charter prohibiting the city from vacating streets in areas near the railway terminals or the river, the purpose of this being to prevent private interests from shutting off public access to the river front. In view of the existing situation, however, the negotiations resulted in the approval of plans submitted by the railways, and a charter amendment removing the restriction as to certain specified sections of streets, with an aggregate area of 658,000 sq.ft., was passed by public vote in June, 1921. This extensive exchange of property is indicated clearly by Fig. 1. On the part of the railways the principal features of the agreement with the city, as adopted on June 20, 1922, are as follows:

FIG. 2.—PASSENGER STATION AND CITY FREIGHT YARD OF NORTHERN PACIFIC TERMINAL CO., PORTLAND, ORE.

traffic will be facilitated by the construction of viaducts carrying streets over the tracks at certain points. A viaduct along 9th St. and crossing the tracks at Front St. is to be built within three years. A viaduct crossing the terminal tracks will form an extension of Lovejoy St. from 12th St. to the Broadway Bridge over the river, an easement for this structure being granted by the terminal company. This will provide a new approach to the bridge, at right angles with the present inclined approach on Broadway, beginning at Hoyt St. The present street beneath this incline will be vacated, as shown. Another viaduct for pedestrians will extend from the station to the bridge.

Street widening is an important part of the general terminal improvement project. When the city widens 14th St. from Hoyt St. to Front St., the railroads will dedicate a 20-ft. strip of land from their properties. For the widening of Hoyt St. from 4th to 14th Sts., after three years from the date of agreement the railroads will dedicate a 10-ft. strip when the city undertakes the work and acquires the other necessary property from private owners. On Sherlock Ave., the city will vacate the west side for use by the railroads and in return the railroads will dedicate a 20-ft. strip along the opposite side, as well as a 50-ft. strip for a connection to Front St., as shown in Fig. 1.

Vacation of Streets—Improvements in railway terminal facilities at Portland have been hampered by the fact that a large part of the area occupied by passenger and freight facilities of the Northern Pacific Terminal Co. and individual railways is laid out in streets and

1. Provision of adequate terminal facilities for both passenger and freight traffic.

2. Dedication to the city of certain railway property needed in future street widening. There are seven widenings in all, but mainly along Hoyt St. and 14th St., and on Sherlock Ave. from 19th St. to Colton St., where the west side of the street will be vacated for railway purposes as noted above.

3. Permission for continued use and maintenance by the city and public service companies of sewers, water mains and other public utilities in the vacated streets, the railways assuming responsibility for damages to these utilities resulting from the changed use of the property.

4. Agreement to pay for the paving of certain streets not vacated in the terminal district, when required by regular street improvement proceedings.

5. Agreement to pay proportionate shares of the cost of the viaducts over the railway tracks at 9th St. and Lovejoy St. when these improvements are initiated by the city. About 80 per cent of the cost of one of these viaducts will be paid by the railways, since the charter apportions 20 per cent of the cost to the city, 20 per cent to the abutting property owners (which are the railways) and 60 per cent to the railways affected.

6. Removal of longitudinal tracks in Front St. so as to leave a width of at least 60 ft. free from tracks. Repaving will be done by the railways. This is an 80-ft. street having docks, elevators and manufacturing plants on the river side and railway property on the opposite side. As a result of the agreement between the railroads

and the city, Front St. is being improved with a 10-in. reinforced-concrete pavement, the relocation of tracks and the installation of safety islands for a line of steel poles. This improvement extends from Glisan St. north to Nicolai St., about $1\frac{1}{2}$ miles, and its cost is estimated at \$240,000.

7. Improving a vacant block in front of the union station to provide adequate parking space for automobiles and giving the city control of the parking on the northeast half of the block (see plan) until such time as it is required for railway purposes.

Under the terms of this agreement the railways are to carry out the main part of these undertakings within three years, or before July 24, 1925. In the negotiations and preparation of plans, each of the five railways had its representatives. The city was represented by O. Laurgaard, city engineer, and the Northern Pacific Terminal Co. by A. E. McKennett, chief engineer. The railway improvement work is carried out under the

Concrete Memorial Bridge Has Attractive Appearance

Washington St. Bridge at Wilmington, Designed as Memorial to Delaware Soldiers, of Pleasing Line and Surface

ONE of the most attractive of the several bridges which have been built as memorials to those who served in the World War is the Washington Memorial Bridge across Brandywine Creek and its valley in Wilmington, Del. The structure is a necessary element in the street plan of the city and the memorial features were added after its initiation at an added cost of about \$56,000. Final cost of the whole project was \$823,000. In keeping with the nature of the bridge special attention was paid to the architectural design, to make it fit more into the park-like nature of the surroundings, and memorial pylons were added bearing the names of

MEMORIAL CONCRETE ARCH BRIDGE ACROSS BRANDYWINE CREEK AT WILMINGTON, DEL.

direction of Mr. McKennett, while the street improvements, viaducts and track work in street areas will be done under the direction of the city engineer.

To Unify Segments of Intercoastal Canal

Col. George M. Hoffman, the district engineer for the War Department at New Orleans, has submitted a preliminary report on the whole intercoastal canal project between New Orleans and Corpus Christi, Texas, and has recommended a survey with the idea of unifying the various segments which make up the waterway. The barge line operations on the Mississippi River, together with the purchase by the Government of three private canals which allow the free use of the existing segment between New Orleans and Morgan City, has greatly stimulated the desire of the communities further west to have the advantage of through traffic.

all those from Delaware who died in the World War as well as the names of the engagements in which Delaware troops were engaged in all of the wars of the United States.

The bridge is 720 ft. long and 72 ft. wide and consists of five reinforced-concrete arch spans; two 70-ft., one 250-ft. and two 85-ft., together with the necessary approaches. Each span consists of three arch ribs, 11 ft., 16 ft. and 11 ft. wide respectively. The deck of the bridge consists of a 40-ft. roadway paved with sheet asphalt, two sidewalks 14 ft. 9½ in. in width and two balustrades 1 ft. 2½ in. in width. The piers of the bridge are on a 30-deg. skew and the large 250-ft. span of 40-ft. rise is one of the longest low-rise skew-arch spans in the United States if not in the world.

There are eight of the large, ornamental pylons or shafts placed on the bridge in line with the railings. Four of the larger shafts are placed over the piers of

250-FT. MAIN ARCH OF WILMINGTON BRIDGE

the large central arch and two of the smaller shafts at each end of the bridge. The large shafts extend 40 ft. above the sidewalk level and the smaller shafts 23½ ft. The bronze tablets are placed on the inside face of the shafts where they can be viewed by pedestrians on the sidewalk. On the inside faces of the smaller shafts are placed bronze nameplates 3x4 ft. On each side of the large shafts and on the approach sides of the small shafts are placed large, ornamental bronze lanterns which are illuminated by a single incandescent lamp of 250 candle-power. On the inside and outside of the large shafts are placed carved cast-stone eagles and shields of a monumental character. The balustrades were made of cast stone to harmonize with the surface treatment of the memorial shafts.

At the center of the span of the large arch a refuge bay was provided on both sides of the bridge by extending the sidewalk slightly beyond the line of the railing, thus forming a vantage point from which pedestrians may view the park below. Refuge bays were also provided at both ends of the bridge. Stone seats were placed in the refuge bays at the north end of the bridge to accommodate pedestrians who might desire to sit and rest. Large ornamental precast stone urns were placed on the end posts of the railing of the refuge bays at the north end of the bridge.

One stairway was provided for the bridge, at the south end on the east side, leading to the park sidewalk and illuminated by two bronze standards with lamps.

The lighting system of the bridge was arranged so as to harmonize architecturally with the pylons and railings, as well as to give the proper lighting effect to the sidewalks and roadway at night. The main lighting system consists of twenty-eight luminous arc lights supported by cast-iron light poles placed on the curb lines of the bridge. The secondary lighting system consists of the incandescent lamps in the twelve large bronze lanterns placed on the shafts and the two bronze standards at the stairway. The two lighting systems are on independent circuits.

The bridge was designed to carry the heaviest modern highway traffic and liberal provision was made for impact and possible future increases in traffic requirements. The assumed loads used in the design were 60-ton electric railway cars entrain on double tracks, a line of 20-ton motor trucks on the roadway at each

side of the tracks and a sidewalk load of 100 lb. per square foot.

The two channel piers, each 20 ft. wide, the shore piers 8 and 9 ft. respectively and the two abutments support the 250-ft. center span with 40-ft. rise, two 70-ft. spans with 15-ft. rise and two 85-ft. spans with 18-ft. rise. Each arch has a center rib 16 ft. wide and two outer ribs 55 ft. apart on centers, that are each 11 ft. wide. The center rib of the 250-ft. span is 6 ft. deep at the crown and 11 ft. at the springing line, and the outer ribs 5 ft. and 10 ft. at crown and springing lines. Over each of these arch ribs and immediately under the floor slab there is a continuous gallery, one of which is reserved for high tension electrical conduits, the second for low tension electrical conduits and the third is used for gas and water mains. The reinforced-concrete floor slab, varying from 12 to 20 in. in thickness, exclusive of floorbeams which occur only at the expansion joints, is supported on longitudinal walls. These longitudinal bearing walls rest directly on the extradoses of the shore spans and are supported by the

ONE OF THE MEMORIAL PYLONS

spandrel columns of the channel span. The floor slab is arched transversely between ribs and is cambered 12 in. to a parabolic curve longitudinally.

The foundations of all piers and abutments were carried down to solid rock at a maximum depth of 5 ft. below water level.

The bridge was built under the direction of the Washington Street Bridge Commission, of which Frederick W. Carpenter was executive officer and consulting engineer. The design was made by Benjamin H. Davis, consulting engineer, New York, with the collaboration of Vance W. Torbert, architect, New York, as the result of a competition held by the commission. The contractor was the Walsh Construction Co., of Davenport, Iowa.

in place prior to this date and the natural method would be to place the steam shovel in the gravel pit on about July 10. The plan was developed along these lines until it became apparent that at some point on the job, the equipment would become "stalled." This condition occurs when excavating equipment approaches a section of road where one-half is covered with green concrete and the other half is open to travel and it is the nightmare of every contractor on a half-section concrete job.

The chart indicated that, to avoid this condition, more excavating work must be done before transferring a shovel to the gravel pit. Consequently, it was planned (see charts) to keep both shovels on the grade until July 15, and to place the first 200 cu.yd. of gravel base by hand shoveling. The remainder of the chart was worked out in much the same manner—selecting the most promising trial plan and working it through

Electrification on South African Railways

THE electrification project for relieving congested traffic conditions on the Johannesburg-Durban main line of the South African Government Railways, in Natal, has been modified materially as a result of the extensive line and grade improvement and double tracking west of Durban, as described in *Engineering News-Record* of Jan. 19, 1922, p. 116. The original plan was to electrify first the section from the port of Durban west 45 miles to Pietermaritzburg. But with the new second track and its more favorable grades on this section the traffic conditions were so improved that electrification was not needed for further improvement.

Serious congestion continued, however, on the single track line beyond Pietermaritzburg. New investigations were made by the consulting engineers, and on

their recommendations parliamentary authority was obtained to proceed first with the electrification from Pietermaritzburg north-west to Glencoe, 171 miles, together with a 2½-mile branch from Merrivale to Howick. The track mileage to be electrified is 245 miles, with maximum gradient of 3.3 per cent uncompensated.

The contract for the supply of seventy-eight electric locomotives for this work has been placed with the Metropolitan-Vickers Electrical Co., Ltd., of England. The normal duty these locomotives will be called upon to perform is for three coupled together to haul a train weighing 1,430 short

FIG. 2—DEVELOPED PROGRESS SCHEDULE FOR EXCAVATION, GRAVEL BASE AND CONCRETE SLAB

to conclusion or to a point where it was necessary to revise it.

A study of Fig. 1 will show that no construction operation takes place on the second half-section within ten days after placing concrete at any point on the first half-section.

The charts are developed together. Thus, on Fig. 2, the excavation progress line changes direction on July 15 when the grader (Fig. 1) is left alone to handle both macadam and earth excavation and again on Aug. 8 when the steam shovel rejoins the grader on the grade.

When construction work was started, the actual daily progress for the three items shown was plotted as a dotted line on Fig. 2. Thus, the progress on a cubic yard basis was immediately apparent.

Fig. 1 was used as a guide to plant layout and enabled the contractor to check the progress of each unit of machinery. It was revised on Aug. 15 because Mixer A could not keep up to schedule and again on Sept. 15 to plan for the addition of a third mixer, when Fig. 2 showed that the amount of concrete being placed by Mixers A and B was insufficient to complete the work within the time limit. It required several weeks to secure a mixer and without the warning given by the charts, it is improbable that it could have been secured in time to place all the concrete before the end of the season, as, in fact, was actually done.

tons from Ladysmith to Pietermaritzburg—about 129 miles—in a little more than seven hours, and in the reverse direction a train weighing not less than 625 tons in about 7½ hours. The locomotives are to be capable of performing the round trip, under these conditions, once every twenty-four hours for six days a week. The gradients on the line between these points are mostly in favor of the fully loaded trains, the average between Ladysmith and Pietermaritzburg being 2.0 per cent.

Electro-pneumatic control will be employed, all the apparatus being mounted in a central compartment which will be locked in such a manner that the driver is unable to enter until the apparatus has been made "dead," thus avoiding all danger of contact with any "live" high-voltage parts. In view of the heavy grades to be met with on the line, the locomotives are arranged for regenerative control.

Most of the contracts for machinery and plant have been let, foundations for the power house at Colenso are being built and work on the building will be started soon. It is expected to have part of the line in operation by June, 1924, and the whole project completed early in 1925. The consulting engineers are Merz & McClellan, of London, England. This work is being carried out under the direction of Sir W. W. Hoy, General Manager of Railways and Harbors, Union of South Africa.

Building a 9-Ft. Siphon on the Hetch Hetchy Aqueduct

Armored With Concrete Outside and Lined With Cement Mortar Inside, Steel Pipe Crosses Reservoir Under 367-Ft. Head

By N. A. ECKART

Chief Assistant Engineer, Hetch Hetchy Project

THE CITY of San Francisco has just completed, as part of the Hetch Hetchy water supply project, an inverted siphon 9 ft. 1½ in. in diameter across the Tuolumne River at Red Mountain Bar. The siphon constitutes a short section of the main aqueduct that will later be built to convey water from Moccasin Creek power house to San Francisco. It is located 5 miles below the power house and will be the connecting link between two sections of a 17-mile tunnel to be driven from Moccasin Creek power house to a point near Oakdale, whence the aqueduct will continue in the form of a steel pipe line across the San Joaquin Valley and toward San Francisco. At the present stage of the Hetch Hetchy project a total of 112 miles of tunnel and

FIG. 1—DELIVERING 9½-FT. PIPE SECTIONS TO THE TRAM
These sections, weighing 12 to 16 tons, were skidded to place in the trench from the tramway running alongside.

aqueduct must still be built before water from Moccasin Creek power house can be delivered to the distributing reservoirs of the present San Francisco water system.

The Red Mountain Bar siphon was constructed in advance of the remainder of the aqueduct because the Don Pedro Dam, just being completed by the Modesto and Turlock Irrigation District, will back the water of the Tuolumne River above Red Mountain Bar, submerging the siphon crossing to a depth of 73 ft., thus rendering uncertain its future accessibility.

The siphon as installed consists of 776 ft. of riveted

FIG. 2—CONSTRUCTION WORK IN SECOND COFFERDAM

The two halves of the river channel were cofferdamed successively; this view shows stream diverted over finished portion of siphon, while work is begun on the far side just unwatered.

butt strap pipe, 9½ ft. in inside diameter, with a plate thickness varying from ⅝ in. to ¾ in. by sixteenths. The pipe is encased in a concrete jacket of 1:2½:5 mix from 18 to 24 in. in thickness and is lined inside with mortar 2½ in. in thickness which was put in to increase the permanency of the construction.

The pipe was delivered, on a siding of the Hetch Hetchy R.R. immediately above the crossing, in sections, normally 24 ft. long, each section being made up of three 8-ft. courses and weighing from 12 to 16 tons, according to the thickness of the plate.

The pipe was laid in a trench excavated in bedrock across the river channel. The lowest point in the siphon is 367 ft. below the hydraulic gradient and hence will normally operate under that head. The stream flow at the crossing during the period of construction ranged from 400 sec.-ft. to 1,100 sec.-ft.

The first step in the field work was the installation of a standard-gage tramway and trestle across the river just above the line of the pipe, the upper end of the tram being at a siding on the Hetch Hetchy R.R. A derrick was installed at this point for handling the pipe directly from the cars to the tram; this also served for handling concrete materials to the tram from the storage bins constructed adjacent to the spur.

At low water cofferdam frames had been built entirely across the stream bed above and below the pipe line and were well braced and anchored to the bedrock. A transverse partition in the center divided the cofferdam into two halves and by the use of sheathing on first one half and then the other the two halves of the channel were successfully unwatered, the trench was excavated, and the pipe laid in the dry. The cofferdams were quite tight, all leakage being handled by one 6-in. and one 10-in. centrifugal pump. While the trench was being excavated an unusually heavy rainstorm, coming earlier than the normal seasonal rains, caused the stream to rise from about 1,000 sec.-ft. to 11,000 sec.-ft. and washed out a short section of the cofferdam. This was quickly replaced with cribs floated into place, where they were loaded with rock, sunk and faced with sheet piling.

The trench excavation across the channel was handled

FIG. 4—SECTION OF COVERING AND LINING OF PIPE

by skips and derricks; the pipe was lowered to place from the tram with the aid of skids down which it was rolled in a bight of cable. Each section of the pipe as it was placed in the trench was riveted and lined up on wooden blocks which were immediately thereafter replaced by concrete piers poured in forms constructed of sacks of sand. These sack forms worked out particularly well in this case where the piers were later to be incorporated into the concrete jackets; the rough surface left by the sand bags giving an excellent bond for the concrete.

When enough pipe had been riveted up to reach from mid-stream to a point above high water, bumped test-heads were riveted to each end of the section and a test pressure of 200 lb. per sq. in. was applied and all joints made tight. A small high pressure single plunger pump with a capacity of 40 gal. per minute, driven by a gasoline engine, was used for testing, and for maintaining the pressure in the pipe while the concrete jacket was being poured and allowed to set.

After pipe laying in the first cofferdam had been completed, a concrete partition wall was constructed between the up and downstream faces of the cofferdam, permitting the pipe to extend through the wall. The river was then diverted over the completed section of the pipe and excavation and laying of the pipe were continued on the other side of the river.

The concrete mixer for the work was located above the highest point of the pipe line below the railroad and all concrete for the jackets on that side of the river was placed directly by chutes. The concrete on the opposite side of the river was delivered in concrete dump cars over the tram line, the cars being loaded from a hopper fed by chutes from the mixer.

The pouring of the concrete was generally continuous, except where the work was stopped for testing purposes. Where a construction joint was necessitated the form was bulkheaded with sacks of sand against which the concrete was poured, leaving a rough surface suitable for bonding when the sacks were removed.

The last operation was the placing of the mortar lining inside the pipe. The form for this lining was sheathed with wooden staves as manufactured for wood-stave pipe. These forms were made up in segments held in place by a collapsible frame. The forms were

centered inside the pipe by means of small precast concrete blocks about 4 in. square formed with tapering sides so as to key into the lining. Light reinforcing was cast in these blocks with projecting ends to bond into the cement mortar. The mortar used in the lining consisted of one part of cement to $1\frac{1}{2}$ parts of sand and was poured through $2\frac{1}{2}$ -in. saddles riveted to the pipe for that purpose at 16-ft. intervals. This mortar was mixed in the concrete mixer and delivered in cars over the tramway.

At the lowest point of the siphon a 12-in. blowoff was installed connecting with a line of 12-in. pipe which was carried up above the level of the reservoir surface. Two valves are installed in this line, one at the upper end and one at the lower level, permitting operation at different reservoir heights. For part of its length this blowoff pipe line is embedded in the concrete jacket of

FIG. 3—SIPHON NEARING COMPLETION.
COFFERDAM REMOVED

Track still to be used for delivering cement mortar lining. Concrete wall in center of channel is a permanent feature.

the main siphon and for part of its length is supported on concrete piers.

The work was carried on by city forces on a day labor basis. W. A. Kraner, acting as superintendent, was responsible for plant layout and field installations. The engineering details and design were by L. W. Stocker, assistant engineer, all under the general charge of M. M. O'Shaughnessy, city engineer.

Decline of Typhoid Fever in Maryland

The typhoid death rate in Maryland declined from 42.8 per 100,000 in 1910 to 7.3 in 1922, according to an advance copy of the 1922 report of Abel Wolman, chief engineer, Maryland State Board of Health. Omitting Baltimore, the rate fell from 43.5 to 10.7. The 1920 rates for the whole state and for the state outside Baltimore were 6.9 and 9.1 respectively.

Technical Sessions Devoted to Discussion of Railway Problems—President's Address
Emphasizes Society Co-operation—Protest on Davis Removal Adopted

Engineering News-Record Staff Report

PLENTY of excursions in delightful weather, a large attendance (over 700), a modicum of business and a surfeit of technical papers which effectually prevented discussion characterized the 53rd annual convention of the American Society of Civil Engineers, held at Chicago on July 11-13. That engineers should "go into politics" in the sense of getting acquainted with men and affairs outside of strictly technical lines was suggested by Mayor Dever in his address of welcome. He referred also to the great importance of the engineer and his work in relation to transportation and municipal development. Incidentally he expressed his willingness to accept advice or suggestions from technically competent men and organizations.

President Loweth on Co-operation—Active co-operation between the various engineering societies was advocated as desirable and necessary by C. F. Loweth in his presidential address. It has been said that if this society had lived up to its early opportunities it might now be the one all-embracing engineering society, but Mr. Loweth questioned both the possibility and desirability of such a result. There is already a large degree of co-operation in regard to technical matters, as illustrated by the Engineering Standards Committee and the National Research Council, but there is need for more concerted activity in matters relating to the public service of the profession and to its general welfare. Certain requirements for such co-operation were noted and it was pointed out that the dangers of a super-organization must and can be avoided. That the decisive vote against joining the Federation (which Mr. Loweth did not mention by name) was based on the plan and not the spirit of co-operation is shown by the history of the Society. A review of the development of engineering societies and the American Society of Civil Engineers was included in Mr. Loweth's address. Increase in membership of the Society slackened after the war but is now again reaching the normal rate of growth. Attendance at the annual conventions, however, is not in accord with membership increase and this matter is having the consideration of the officers. Under the new plan of divisions for separate subjects there are now five divisions and Mr. Loweth expects that others will be organized.

Many Papers But No Discussion—Engineers at this convention were subjected to endurance tests in the two morning sessions. At the first session, six papers were presented after the opening ceremonies and at the second session no less than ten papers were crowded into a 3-hour stretch. In order to keep within even these long limits the papers had to be read hurriedly, some in full and others in abstract. There was no opportunity for discussion and it is creditable to the members that so many sat out to the end. With one exception the papers were read by their authors. All the papers were good, but in the aggregate they were too long and too solid. Two or three at each session would have received better attention. Further, if the six papers on Chicago terminals had been compiled into one fairly long paper,

with a minimum of statistics but with all the lantern slides used in the separate papers, the subject would have been more interesting and have occupied less time, while the audience would have had a much better comprehension of the subject.

Railroad Transportation—Public phases of the railroad problem were presented in a group of papers on July 11. That the railroads should be freed from political attack and agitation in order that they might carry on their work in the interests of the public and the investors, was urged by C. A. Morse (C., R. I. & P. Ry.) in dealing with "Consolidation of Railroads." In a second paper on this subject Professor Worley (University of Michigan) said the proposal for a score of groups is too drastic; he thought that at first there should be nearly a hundred groups. In reviewing "Federal Valuation of Railroads," E. F. Wendt (Washington, D. C.) pointed out that the value of the property is fundamental to public regulation in such matters as rate making, capitalization, consolidation, joint use of terminals and construction of new lines. He believes that the aggregate value of the railroads as determined by the Interstate Commerce Commission will substantially equal their capitalization.

Transportation as related to national progress was reviewed interestingly by J. G. Sullivan (Winnipeg). Railroad construction has been a great factor in this progress, but if carried to extremes it may be actually detrimental to the public interest. This condition is illustrated in Canada, where railway development has aided settlement and prosperity to a high degree, but where inflated construction under government guarantee for political purposes has now burdened the country with an annual deficit of \$60,000,000 to \$80,000,000. That investments in railroad securities include those of a great army of small investors (representative of "the public") and are not merely those of "big capital" was pointed out by John W. Kendrick (Chicago). Railroads as arteries of commerce were discussed in a paper by J. R. Bibbins (Washington, D. C.) which was read in his absence.

Railroad Terminals—That terminal facilities were needed badly was the theme of a group of ten papers crowded into the morning session of July 12. After an opening paper by H. R. Safford (C., B. & Q. R.R.) the subject of "Principles of Terminal Station Design" was discussed by Alfred Fellheimer (New York) in relation not only to broad features such as public relations, utilizing air rights and merging of terminals due to consolidation, but also as to traffic considerations and station facilities. Improvement and ultimate unit operation of the complicated freight terminal facilities of St. Louis was advocated by Charles E. Smith (St. Louis) on the basis of the comprehensive report abstracted in *Engineering News-Record* of July 6, 1922, p. 17. In "Street Development in Relation to Railroad Terminals," J. L. Crane, Jr. (Chicago) pointed out that the intensive use of limited city areas has produced more traffic than the streets can properly accommodate.

This difficulty may be overcome in many cases by railway and municipal authorities co-operating in the joint planning of terminals and street systems.

Six papers on the Chicago railroad terminals dealt with specific works and prospects but involved considerable repetition in explaining local conditions. That the new Union Station will be a one-level station in spite of its size was one of the points brought out by J. D'Esposito, chief engineer. Some of the new tracks are already laid and the headhouse is under construction. In regard to the new Illinois Central R.R. terminal works, representing the most extensive of the Chicago projects, D. J. Brumley, chief engineer of terminal improvements, estimated that the electrification will result in speeds as high as 57 m.p.h. on the suburban express runs and that such service will be in operation in three years.

An unusually broad-minded attitude is shown by the city of Chicago in requesting the railroads to co-operate in a study of the improvement of the street layout and complicated terminals adjacent to the south side of the loop district, including three passenger stations. This problem was presented in two papers by R. H. Ford (C., R. I. & P. Ry.) and F. E. Morrow (C. & W. I. R.R.). Projects for rail and water terminals in the Chicago district were described by Major Rufus W. Putnam, U. S. Engineers. Finally the original and adopted designs of the great freight station and warehouse built at Chicago a few years ago by the Pennsylvania R.R. were described by W. L. R. Haines (Pittsburgh).

Business Affairs—Only a few minutes were devoted to a business meeting after the protracted morning session of July 11, the most important action being the adoption of a resolution and statement prepared by the Board of Direction in protest against the summary dismissal of A. P. Davis as Director of the U. S. Reclamation Service. Another resolution expressed the Society's feelings at the murder of John E. Shoemaker in the massacre at Herrin, Ill., while in the discharge of his duties. This resolution also deplored the fact that though this outrage occurred a year ago, the State has been unable to bring the guilty parties to justice. At the closing session a resolution was adopted regarding the death on July 11 of Captain Robert W. Hunt, the noted engineer and metallurgist. In addition to the actions of the Board of Direction noted last week, the board adopted a resolution of protest at the attitude of the municipal authorities of Pittsburgh in intrusting the design of large bridges to architects.

Brief and lightly attended meetings of the highway, sanitary and city-planning divisions were held in the afternoon of July 11, when the power division also held a meeting for the presentation of papers on power development, by W. L. Abbott (Chicago) and on ice problems of hydro-electric plants, by W. T. Walker (Minneapolis).

The sanitary division accepted the invitation of the Sanitary Association of New Jersey to co-operate in working out sewage disposal problems in that state and authorized the appointment of a committee to work for a bill giving engineers in the U. S. Public Health Service equal status with that of the medical officers. The matter came up through a letter from Sol Pincus outlining a course of action and also by reference to the division by the Board of Direction. S. A. Greeley reported ready response from sanitary engineers in contributing for the proposed annual medal for the best contribution on the fundamentals of sanitary engineer-

ing. Opinion seemed to favor calling this the Rudolph Hering medal. The highway division discussed proposed activities of the division and the program of the Richmond convention, opinion on the latter being that "bond issue" topics had better be omitted.

Excursions included trips to various local industries and points of interest, and there were two informal dinners followed by dancing. For July 13 two all-day trips were arranged: one on a steamer cruising along the lake front to show the numerous park improvements and industrial developments, the other by rail to Milwaukee to inspect the sewage treatment plant.

Pavement Undermined by Large Sewer Withstands Traffic

ALTHOUGH unsupported for an area 17 ft. wide and 25 ft. long, a 6-in. concrete pavement slab in North Sixth St., Sheboygan, Wis., for an indefinite time withstood heavy traffic which included a 7-ton power flusher carrying 5 tons of water. The pavement was undermined by the sandy material finding its way into an

BREAKING DOWN UNDERMINED UNDamaged CONCRETE PAVEMENT TO MAKE SEWER REPAIRS

Cavity 25 ft. long and 17 ft. wide formed by material washing into sewer was not disclosed until sewer became clogged. A 7-ton power flusher used this street for some time before the cavity was discovered.

18-in. sewer 13 ft. below grade. The cavity was about 8 ft. deep when discovered through a clogged sewer.

The paving laid in 1921 was 6 in. thick at the center rather than the usual 8½ in. required by specifications because it was laid over 20-year old macadam which was considered to have a good bearing power. However, C. U. Borley, city engineer, states that the macadam at the center of the street was nearly all removed in grading to subgrade and some doubt was expressed at the time of the sufficiency of using only a 6-in. slab on a 40-ft. street with a 5-in. crown making a decidedly flat arch. As shown in the photograph, a transverse expansion joint cut entirely through the pavement 3 ft. from one end of the cavity.

For the base the mix was 1:3:5 and for the 1½-in. top it was 1:2:4. The mesh reinforcing was placed near the top of the slab to meet temperature stresses so it had little value when the slab acted as a beam.

In removing the slab to make repairs to the sewer an opening was cut 20 ft. long with sledges and bull points. This narrow opening was then widened with sledges breaking the concrete into small pieces without developing any large cracks or getting out any large pieces.

Chicago City Council Plans Unified Transit System

To Rearrange and Extend Existing Lines—Universal Free Transfers—Few Subways—Interchange with Electrified Suburban Lines

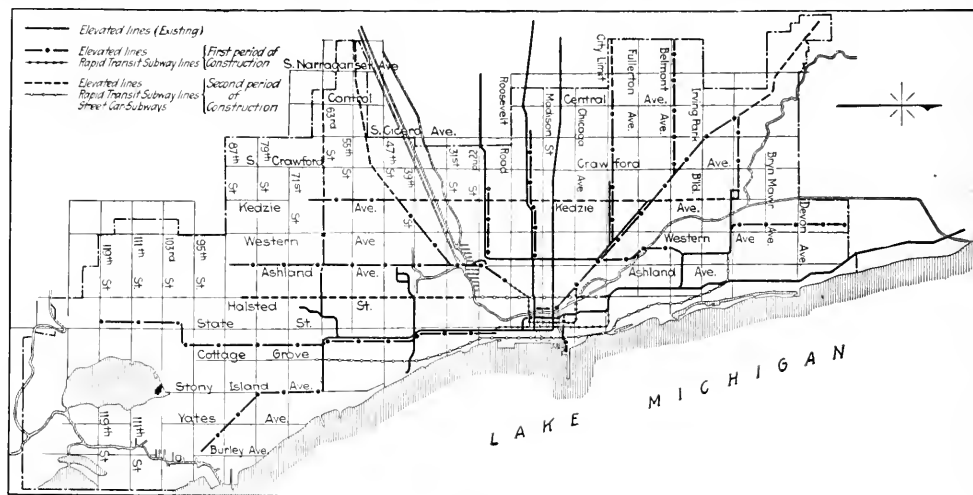

Abstract of the report and recommendations on a physical plan for a unified transportation system for the city of Chicago, made by R. F. Kelker, Jr., chief engineer of the committee on Local Transportation of the City Council of Chicago.

THE PLAN of the local transportation committee of the Chicago City Council to improve the transit situation of the metropolitan district is at variance with most former proposals in that it proposes modification and extension of the existing elevated and surface lines, with the addition of a comparatively small mileage of new subways, rather than a large mileage of new subways and the abandonment of a great deal of the existing systems. It calls for the introduction of universal free transfers between the present surface and elevated lines as a means of giving immediate relief from the surface congestion in the Loop District and of speeding up the passenger movements. The plan also proposes as a future development an interchange between the electrified suburban lines of the trunk railroads and the city rapid transit whereby rapid transit

the first two was based on the demand of earlier years, and with the exception of the rehabilitation and extensions made between 1907 and 1911 no changes have been made to meet the demands of the expanding city.

The Chicago Elevated Railways, a voluntary consolidation of the four former elevated companies, comprise the rapid transit system of the city. The combined lines have 162 miles of track but carry only 17 per cent of the revenue passenger traffic. The growth of traffic has not kept pace with the increase in population due to the limited terminal facilities of the central business district and the financial inability of the companies to extend their lines. The reason for not obtaining the maximum capacity is apparent when it is realized that thirteen tracks converge on the Union loop, a double track loop operating in the central business district.

The Chicago Surface Lines, a similar consolidation of four surface railways, comprise 1,060 miles of single track, and carry 71 per cent of the traffic. These railways present a nearly uniform development of trunk and cross-town lines which are intersected by lines on the important radial

GENERAL PLAN OF THE PRESENT AND PROPOSED RAPID TRANSIT LINES

trains can be routed to suburban points and suburban trains can have access to the entire rapid transit system.

The metropolitan district of Chicago as assumed for the purposes of this report has an area of 275 sq.mi., and a population of approximately 3,000,000. It is estimated that the population will be 5,000,000 in 1950. The district is peculiar in that it is semi-circular in form with the central business district, the normal center of the area, located at the extreme easterly edge and close to Lake Michigan. Obviously then the length of haul is considerably greater than if the area was circular in form. At present the central business district is restricted to the area bounded on the east by the railroads along the shore of Lake Michigan, on the north and west by the industrial district along the Chicago River, and on the south by the railway terminal area. Its growth is practically confined to this area by the fact that with one exception the only rapid transit lines in the city terminate there. The one exception is the stockyards branch.

The present city transportation system is made up of surface lines, elevated lines, and bus lines. The layout of

streets. The limited capacity of the elevated has forced an unusually large proportion of the people to use the surface lines but even so 30 per cent of the lines do not pay the cost of operation. Single fare transfers are used on both elevated and surface lines but the two systems are in competition and do not exchange transfers. Two fares are therefore necessary in order to get the full benefit of the two systems. This condition results in the remarkable length of the average ride on surface lines of 4.2 miles. Bus lines now operate over 23 route-miles and carry 1 per cent of the passengers. The remaining 11 per cent are carried by the suburban lines.

The result of all these conditions is that the maximum number of cars that can now be operated on both the surface and elevated routes which terminate in or pass through the central business district is determined by throats or controlling points in that district. As the present outlets from this congested district are used nearly to their practical limit the capacity of these routes throughout their length is thus fixed by these controlling points. The elimination of such controlling points will

be accomplished by the development of the plan recommended in this report.

Elements of the Plan—The fundamental elements of the plan are as follows:

- (a) Long haul traffic carried on rapid transit lines,
- (b) Short haul traffic carried on surface lines serving as feeders to the rapid transit lines,
- (c) Transfers between surface and rapid transit lines to facilitate (a) and (b),
- (d) Unification of independent systems to eliminate competition and the resulting needless duplication,
- (e) Transportation system planned in advance of traffic demands,
- (f) Use of existing structures as far as possible to form part of the complete system,
- (g) Connection of various outlying commercial centers in such a manner as to provide rapid transit without passing through congested centers.

The fundamental principle of the whole plan is the use of existing facilities as far as possible. The committee justifies this idea by the fact that a former proposal to construct an independent system of subways would cost \$550,000,000 more than the proposed system. It also points out that approximately four miles of elevated railway can be constructed at the cost of one mile of subway.

The proposal to build street car subways in the central business district is postponed to the second period of construction as they are expensive and not economical to operate and may be found unnecessary by that time. The proposal to scrap the Union Loop and replace it by subways is also considered unjustified for some years to come.

The key to the solution of the terminal problem is found in providing four tracks through the central business district for North and South Side trains by devoting two tracks of the Union Loop in Van Buren St., Wabash Ave. and Lake St. to the exclusive use of West Side trains. This will be accomplished by the construction of a two-track subway in State St. and in North Ave. from a connection with the South Side Elevated to a connection with the Northwest Elevated, and by the construction of a two-track elevated railway on Wells and Polk St. to a connection with the South Side elevated.

Bus lines are recommended only for use as feeders in outlying districts until the density of traffic along their routes will justify the construction of surface lines.

When the excess capacity of the city's urban lines is sufficient to accommodate all or part of the suburban traffic the committee recommends that a study be made to coordinate the unified city system with the electrified suburban railroads. It outlines a plan whereby a connection would be made with such railroads about five miles out from the center of the city, where rapid transit trains and suburban electric trains could interchange, thus making the whole rapid transit system available to the suburban service and reducing the concentration at the railroad terminals. This will make it unnecessary for the railroads to acquire more costly property for additions to their city terminals.

The Comprehensive Plan—The committee recommends that the construction program be divided into two periods as follows: A First Period of Construction, which includes such parts of the plan as are urgently required and can be definitely located at this time; and a Second Period of Construction, which includes the remaining parts of the plan, adjusted to suit the changes that will occur before that time. At the end of the two periods the city will have a complete Unified Transportation System to accommodate the needs of Chicago when its population shall have reached 5,000,000 which is estimated to be about the year 1950. This system is shown for the whole city in Fig. 1. It includes the following divisions:

- (a) Rapid transit subways:
 - (1) The State Street subway
 - (2) The Clark Street subway
 - (3) Cottage Grove—Broadway subway
 - (4) Halsted Street subway
- (b) Elevated Railroads:
 - (1) Mid-City trunk line

- (2) Northwest Side lines
- (3) Southwest Side lines
- (4) North Side and South Side lines
- (5) West Side lines
- (c) Additional street railways
- (d) Street car subways in Washington and Jackson Streets in the central business district.

TABLE I—ESTIMATED COST OF UNIFIED SYSTEM

	First Period	Second Period
Rapid transit subway	\$44,330,000	\$75,810,000
Elevated railways	71,173,000	30,115,000
Surface railways	13,770,000	8,595,000
Cars	72,750,000	27,600,000
Substations, shops, yards	15,820,000	6,000,000
Street car subways	None	6,870,000
	\$217,843,000	\$154,990,000
		217,843,000
		\$372,833,000

The estimated cost, including cars, yards, substations, and terminals is shown in the accompanying table.

Results Accomplished—Unification of all the existing lines, and the use of single-fare transfers will give some immediate relief and will be of added advantage as the system is expanded. Lack of unification has resulted in

TABLE II—MILES OF SINGLE TRACK

	Existing Systems	First Period of Construction	Second Period of Construction	Periods Total	Unified System Total
Rapid transit subways	None	17.6	37.3	54.9	54.9
Elevated railroads	162.0	137.0	67.2	366.2	366.2
Total rapid transit	162.0	154.6	104.5	259.1	421.1
Street car subways	None	None	2.5	2.5	2.5
Street railways	1,060.0	133.0	95.5	248.5	1,308.5
Total mileage	1222.0	307.6	202.5	510.1	1732.1

85 per cent of the people riding on the surface lines, the more expensive means of transport, while the elevated lines were not used to advantage.

Transfers and the relocation of surface and elevated stations will make it possible for more people to use the elevated lines for the long part of their ride and will consequently make it possible for 70 per cent of the present number of surface cars now operating in the central district to handle the traffic which will still have to use them.

Other benefits of the unified system will be:

- (a) Faster running time, a reduction of the long-haul riders' time from an average of forty-five to twenty-five minutes;
- (b) Increased capacity—by eliminating the throats or controlling points of the central business district which are now taxed to capacity, and by adding lines which will make the joint capacity at the end of the first period of construction double the present capacity;
- (c) Development of business centers;
- (d) Development of residential districts;
- (e) Relief of the congestion in the central business district, by the reduction of the number of surface cars, and by making it possible for the district to expand across the Chicago river to the north;
- (f) Reduction of operating expenses, as the operating cost per mile on rapid transit lines is only 75 per cent of the cost of surface lines and the unification of the system will shift the bulk of the passenger mileage to the rapid transit lines.

Engineer-Legislators in Canada

Engineers in the federal and provincial legislatures of Canada total 12 out of a total membership of 915, or about 1.3 per cent, according to a count made by *The Canadian Engineer*. In the federal parliament there are two engineers in the senate and three in the house. Of the nine provinces Quebec and British Columbia each has two engineer-legislators; New Brunswick, Ontario and Alberta one each; and the other four provinces none.

Operating Costs on Grinder Used To Make Sand From Basalt

Absence of Sand at Copco Dam Necessitated Grinding Up Rock for Concrete Aggregate—Sand Cost Was \$1.10 per Cu.Yd.

By P. O. CRAWFORD

Chief Engineer, California Oregon Power Co.

IN THE construction of the Copco Dam on the Klamath River in northern California some years ago, the California Oregon Power Co. was unable to locate a deposit of sand near the dam suitable for concrete and finally installed two Williams Universal No. 3 sand grinders. For the first three months black volcanic cinder was put through these without good results. The cinders were moist and clogged the grates, cutting the sand production very low and wearing the bars and hammers excessively. Drying the cinders did not materially improve conditions. However, the same grinders were later used to make sand from a hard basaltic rock, found at the site, which has a specific gravity of about 2.7. This sand was very satisfactory and, owing to the larger percentage of fines, produced a denser concrete than would have been secured with river sand. In view of this success, when it was decided in 1922 to add to the power house and increase the height of the dam, one of the sand grinders was again used with the results cited in the following.

This time the grinder was mounted just below the delivery of the belt conveyor from the gyratory crusher and the supply chute was so arranged that any portion

provided, otherwise in case of worn or broken bars a considerable volume of coarse material might be delivered to the bunker before the variation in the product was discovered.

Provision must also be made for keeping the grinder product dry, otherwise it becomes hard to handle because of the percentage of dust contained. The irregularity of the product and the occasional large pieces made it preferable not to use this sand for finishing work such as floors, etc., although doubtless this would not have been the case with soft rock.

The separation of grate bars as supplied for renewals was $\frac{1}{4}$ in. and it was found desirable on this work to increase this opening to $\frac{1}{2}$ or $\frac{3}{4}$ in. by welding lugs to the ends of each bar to serve as spacers. With new liners and hammers the clearance between the ends of hammers and the first grinding plates is about $\frac{1}{4}$ in. This clearance and the space between bars was found to increase rapidly so that a new set of grate bars in the bottom half of the grinder was required every two to two and a half weeks. Any bars not entirely worn out when these renewals were made were placed in the upper half where there was less wear.

The hammer bars in this machine are arranged so that as the outer end wears they may be moved out from the center $\frac{1}{4}$ in. at a time for a total gain of 3 in. In grinding this material it was necessary to move them out one hole about every week and after each two moves it was found best to take the hammers out and have the tips squared off as they wore to a point which resulted in a cutting rather than a crushing blow. When the hammer bars had worn too short for further service two such stubs were welded together to make a single new bar.

In a period of seven months one of these grinders turned out approximately 3,600 cu.yd. of sand operating about 180 nine-hour days at a cost of \$3,031 for new parts and \$700 for labor on operation of repairs and installation of new parts. This total gives a unit cost of 84 cents per yard for new parts and 19½ cents per yard for labor on repairs and renewals. The total cost of sand secured in this way was put, in round figures, at \$1.10 per cu.yd. This figure does not include any quarry cost nor power for the 50-hp. motor used to drive the grinder. It is safe to say, however, that any imported sand of equal quality would have cost at least twice as much as this even with quarry and power costs added.

During this seven-month period there were placed in the grinder 5½ sets of hammers and six sets of grate bars. Approximately 110 man-days were required for these changes and renewals and also for repairs including blacksmith work in welding and dressing hammers.

Low Typhoid Death Rate for England in 1922

The typhoid death rate for England and Wales was 1 per 100,000 in 1922, according to a return issued by the registrar general. With the single exception noted below, and omitting decimals, there was no variation either by seasons or for the total as compared with the urban population. The variation mentioned occurred in the second quarter of 1922, when the rate in the "smaller towns" (20,000 to 50,000 population) was 2 instead of 1 per 100,000. The total mid-year population was estimated as 38,150,000 of which 19,170,420 was in 105 "county boroughs and great towns" and 4,931,620 in 155 "smaller towns."

MECHANICAL ANALYSES OF SAND FROM GRINDER
(Percentage by Weight, Passing Through Each Screen)

Screen Mesh Per Inch	Average of 1917 Tests	Average 5 Runs Apr. 8, 1922	Average 4 Runs Apr. 12, 1922	May 10, 1922	May 8, 1922	Average 8 Runs Nov. 22, 1922
	Per Cent	Per Cent	Per Cent	Per Cent	Per Cent	Per Cent
4	60.4	70.8	21.1	63.5	66.2	72.5
20	44.5	47.6	12.2	48.5	56.2	50.7
30	36.6	38.6	10.8	39.6	51.7	45.8
50	28.8	31.5	10.2	27.0	48.0	35.4
100	20.8	13.5	3.2	6.5	19.3	23.6

from zero to 100 per cent of the crusher product could be diverted to the grinder. Ordinarily the chute was set so that 40 to 45 per cent of this crusher-run rock, varying in size from dust to 5-in. rock with some larger pieces, went into the grinder. The average size of this material was between 1½- and 2-in. rock.

The resulting sand was quite variable due to the wearing of grate bars, hammers and liners and was subject to sudden changes due to the wearing out or breaking of bars, in which cases rocks up to 1 in. in diameter would come through. Trouble was also caused whenever pieces of drills, etc., inadvertently got into the feed. The variation in mechanical analyses is shown in the accompanying table.

Although recognizing the advisability of feeding only small rock through the grinder so as to keep the wear down to a minimum, in this case it was found best to pass part of the fines from the crusher to a $\frac{1}{4}$ -in. mesh revolving screen and to use the portion passing through the screen as sand. These screenings constituted about 25 per cent of the sand used on the job; the remaining 75 per cent was furnished by the grinder.

It should be noted that if the product of a grinder operated in this manner is to be stored in a large sand bunker some means of keeping a constant check on the grinder product before it reaches the bunker should be

Air Vibrations Due to Fluttering of Water Sheet Over Dams

Partial Vacuum Between Water Sheet and Face of Dam Produces Waves That Rattle Objects in Nearby Buildings

By FREDERIC I. WINSLOW

Division Engineer, Metropolitan Water-Works, Framingham, Mass.

WHAT APPEARS to be a strongly marked case of the comparatively rare phenomenon of vibrations transmitted through the air to a considerable distance occurs about once a year on the Sudbury section of the Metropolitan Water-Works, at Framingham, Mass. The occurrence is noted on two dams, each having a face with a batter of but one in twelve (see sketch). A third dam of similar section but having the sheet of water broken by a continuous rod passing just above the crest of the dam is free from such vibrations. As a result of these vibrations windows rattle, dishes sometimes fall from shelves, and insecure piles of boxes topple over, when the effect is most pronounced, over a mile from the dam. At times the sound effect is similar to that produced by an explosion except that it is more like a series of mild explosions. A like phenomenon has given trouble near Fitchburg and slight vibrations are reported from a few other dams.

As the dams are built on compact sand and no rock is in evidence, the only explanation of the phenomenon is a partial vacuum between the sheet of water and the face of the dam which causes a fluttering which appears to operate on a large scale much as does the diaphragm of a telephone receiver. The sheet of water flowing over the dam and vibrating uniformly, imparts to the atmosphere a series of waves which resemble wave translation in water, or sound waves in the air. Another analogy is the electromagnetic waves produced in wireless telegraphy by a spark discharge which resembles those produced in the atmosphere by an explosion, or the continuous wave produced by an electric arc or the oscillating tube may present a parallel with the waves produced by a fluttering sheet of water.

The dam where the phenomenon is more frequently observed—and this is due to the fact that this dam is used to discharge all the waste from Sudbury River—is 168.67 ft. in length and has a fall of water of about 11 ft. Little vibration is felt until the volume of water passing over the dam amounts to over 300 m.g.d., corresponding to a 6-in. depth of water on the crest. At one time it was attempted to mitigate the effect of the vibrations, as at least one complaint was made of rattling noises at night, by introducing timbers under the sheet of water so that air might freely enter, but this was abandoned.

Several engineers of note in charge of large dams have never had similar vibration experiences and some have never heard of its occurrence anywhere. At Lawrence, Mass., vibrations have been observed when the volume of water was sufficiently large, or when the depth of water is about 1 ft. At Lowell, Mass., the fluttering has been observed when the flashboards have been raised several feet in height and there is 6 in. of water flowing over the dam—generally with a slight breeze at the same time. Vibration has also been observed at several vertical timber dams along the Pawtuxet River in Rhode Island—in every case where there is little or no opportunity for access of air at the ends

of the dam—but the vibration has not been so pronounced as to be noticed in the neighborhood.

A more marked case has been reported from Fitchburg, Mass., where it became necessary to devise some method of preventing the trouble. The Fitchburg dam was a small concrete structure (see sketch) on the North Branch of the Nashua River, about 150 ft. long and with a maximum height of 15 ft. The vibrations were at their worst when the water was about 6 in. over the crest, and became less as the depth of flow either increased or decreased. Near this dam, the rattling of windows and general noises in the houses be-

SECTIONS OF FRAMINGHAM AND FITCHBURG DAMS

When water flowing over the dams reaches a depth of about 6 in., air vibrations occur which are transmitted for considerable distances, and sometimes rattle windows and dishes in houses. Note almost vertical downstream face of the two dams.

came so marked that the residents threatened legal action, and an engineer was called in to devise a remedy.

Probably in the cases just mentioned, the lengths of the waves propagated are comparatively long, and these, if occurring at the proper periods, would set material objects in motion and cause them to vibrate in unison with the wave period, in exactly the same manner that a sound wave causes a wire tuned to the proper period to vibrate at that period.

It may not be amiss to refer to a somewhat different variety of movement set up within a water-works system leading to complaints of inability to rest at night owing to noises set up in water pipes in dwellings. Some years ago on the Boston water-works, a complaint of this kind was made, and on investigation it was found that with a hydrant half-opened at night, in order to fill a skating pond at a public park, such a rattling occurred in the meter and pipes in a dwelling about a quarter of a mile away as to demand some relief, which was simple in this case. The tenant of this house happened to be of a sensitive organization, and alone noticed it, as no one else in neighboring houses, even after questioning, appeared to be cognizant of the phenomenon.

Membership of Boston Technical Society

According to the recent report of the executive secretary, the Affiliated Technical Societies of Boston have a total membership of 3,575 as of April 1. However, as there are a number of duplications in the affiliation the total net membership is 3,168. The distribution of members is as follows: Boston Society of Civil Engineers, 932; New England Water-Works Association, 733; Plant Engineers Club, 24; American Institute of Electrical Engineers, 581; American Society of Mechanical Engineers, 913; American Society of Civil Engineers, 140; American Institute of Mining and Metallurgical Engineers, 56; Massachusetts Chapter, American Society of Heating and Ventilating Engineers, 35; and Boston Chapter, American Association of Engineers, 161.

Engineering Literature

A MONTHLY REVIEW OF BOOKS AND A LISTING OF NEW PUBLICATIONS

Hydrogen Ions

REVIEWED BY HARRY E. JORDAN

Sanitary Engineer, Indianapolis Water Co., Indianapolis, Ind.

THE DETERMINATION OF HYDROGEN IONS—By W. Mansfield Clark, M.A., Ph.D., Baltimore, Md.: Williams & Wilkins Co. Cloth; 6x9 in.; pp. 480; illustrated. \$5 in United States, Canada, Mexico and Cuba; \$5.50 elsewhere.

The second edition of this book shows no material textual change or addition, but more than nine hundred new references have been added to the eleven hundred appearing in the first edition [which was not noted in these columns—EDITOR]. This in itself is significant of the real importance of the subject matter of the text. Glancing over the Bibliography one realizes anew how wide and active and fruitful is the interest in this subject. The *Journals* of the American Chemical Society, of Biological Chemistry, of Bacteriology, as well as the more practical *Journal* of the American Water Works Association, rarely issue a number in which there does not appear an article based upon studies involving hydrogen ions.

The text is formidable, not in size, rather in its conciseness and strict adherence to the presentation of the scientific facts. An able critic of the first edition regretted that a few brief chapters of simplified theories were not added; many users of the text have regretted that Clark did not add a simple statement on the use of the potentiometer and on the care of electrodes. Those who know Clark realize that he will not deviate one iota from the more purely scientific and theoretical basis by any concession to the practical side. Fortunately there now exists in the literature enough information, simply stated, to guide the somewhat faltering approach, let us say, of the chemist who, instructed in the primitive empiricism of qualitative and quantitative analysis twenty years ago, finds it not easy to keep abreast of the science in its present-day form, admixed as it is with physics and mathematics.

In the field of sanitary engineering the determination of hydrogen ions has had a tremendous influence—not the least important of which has been the mental stimulus to the engineers themselves. It has done more to furnish tools for investigation and rational study of problems of sanitation than anything, perhaps, since the first plate count of bacteria was made. Naturally, there have been a few ill considered applications of these data to certain projects—in one notable case retarding the construction of a much needed water purification plant.

While the applied theories are yielding valuable information in studies of iron removal, softening, and coagulation processes, it appears that no material change in purification structures will develop. As to methods of correctly preparing water for filtration, every day in the year, as well as prevention of red water troubles in distribution systems, knowledge of Clark's text and the allied literature is of great value.

The usefulness of the next edition could be increased

by expanding the Bibliography to a series of brief abstracts of the references cited, as has been done in other books. Although this would mean a lot of drudgery on the part of the author it would vastly increase the service qualities of the enlarged book.

Valuable Researches on Ventilation

VENTILATION: Report of the New York State Commission on Ventilation Appointed by the Governor of the State of New York at the Request of the New York Association for Improving the Condition of the Poor and Supported by the Milbank Memorial Fund, C.-E. A. Winslow, Chairman, New York: E. P. Dutton & Co. Cloth; 7x10 in.; pp. 620; 134 line cuts and halftones. \$15.

Keep cool. This is the fundamental conclusion of this report as regards ideal conditions of ventilation. Next in order of importance is keep dry and don't worry much about over-dryness—reference here being made to relative humidity. Forget carbon dioxide *per se*; forget also in large degree organic and other impurities in air except when these go to extremes and even then regard these chiefly as having an unfavorable effect upon appetite and inclination to work. Such, in brief, are the main conclusions drawn from the interesting historical review of ventilation theory up to the date of the experiments forming Part 1 of this book and from studies on the effect of various air conditions conducted by the New York State Commission on Ventilation.

That window ventilation is the best method for school rooms is the main conclusion drawn from the many experimental and other data given in the 400 pages of Part 2 of the volume. That is, having established the main desiderata for ventilation in general, the commission devoted the major part of the rest of its studies to a consideration of how a supply of cool air, with reasonably frequent changes, can best be secured for school rooms. The Commission summed up its conclusions on this point as follows:

"In general, therefore, we are forced to conclude that window ventilation with ample direct radiation, window deflectors, and adequate gravity exhaust, seems the most generally promising method for the ventilation of a class room where local conditions permit its use." The conclusion just quoted is based principally upon studies of the sort of ventilation outlined compared with plenum and fan ventilation. Some attention is given to fan exhaust, on which the Commission has this to say: "Such data as we have obtained are not particularly promising along this line." It should be understood that these main conclusions are qualified in various ways by the more detailed discussion given in the report, and stress should be laid upon the fact that so far as window ventilation is concerned its application here is limited almost wholly to school rooms.

The New York State Commission on Ventilation was appointed some eight or nine years ago by the Governor of New York and under the other conditions stated in the heading to this notice. It serves without expense to the state.

The opening chapter of the report is a most excellent and interesting review of the historical development of knowledge in regard to the physiological influences of ventilation, compressed within a very few pages. Those who cannot read French and German will be annoyed, to say the least, by the fact that relatively extensive citations in these languages are given without translation and sometimes without any summary. Another source of annoyance—and this extends throughout the whole of the text of the volume—is the long measure employed, the lines being 5½ in. long and therefore difficult to read.

The division of the report into two main parts has already been indicated. It has also been intimated that each part contains many detailed data. These consist of minute descriptions of the experimental work conducted and the apparatus used together with tabular logs. Further details are given in an appendix.

The conclusions drawn by the Commission in favor of window ventilation of school rooms were very promptly and vigorously challenged at the annual meeting of the American Society of Heating and Ventilating Engineers at Chicago in May, and the president of the society was authorized to appoint a committee to consider the report and submit recommendations regarding it at the next annual meeting. (A brief summary of the discussion may be found in *The Heating and Ventilating Magazine* for June.) It was urged during this discussion that (quoting from the magazine just named) "the Commission had exhausted its funds before completing its work and that the story might have been very different if the plans, as originally outlined, of testing school buildings under a wide variety of conditions, had been carried out." It should be noted that one of the members of the Commission, D. D. Kimball, New York City, is a member of the society.

An important point not yet mentioned regarding the conclusions of the discussion is that observations over some weeks of time showed 18 per cent more absences due to respiratory illness and 70 per cent more respiratory illness among children in the "warmer fan-ventilated rooms" than in the window-ventilated rooms, even though the latter had less per capita floor space than the former.

The report as a whole is a most valuable piece of work and will repay study. Good summaries are given at the end of each chapter. These will enable anyone who cannot read so voluminous a report in detail to get the main results and conclusions in a short time.

An Engineer's Brief for a Stable Dollar

EVERYBODY'S MONEY: What It Is, What It Does and What Should Be Done with It—By Ernest McCullough. New York: G. P. Putnam's Sons. Cloth; 6x8 in.; pp. 175; two plates of line cuts. \$1.75.

After writing a considerable number of books on engineering and closely allied subjects, and after war and post-war experience of the evils of inflation and deflation, Mr. McCullough has attempted what may perhaps be best and most briefly described as a popular exposition of Prof. Irving Fisher's plan for Stabilizing the Dollar—recently set forth by the latter in a book bearing the title just quoted and also embodied in a congressional bill. The Fisher plan proposes basing the amount of gold in a standard dollar on a price index, the index to be computed six times a year and the num-

ber of grains in a dollar and also the number of dollars in the treasury to be changed accordingly.

To lead up to his final chapter on The Natural Standard of Value, the author reviews briefly, with many apt illustrations, both homely and statistical, the following main topics: Prices and value, money—metal, paper and bank—foreign exchange, war inflation, the business cycle and the price index. A point urged repeatedly throughout is that the voters of the country should gain a knowledge of the fundamentals of the subject and then take the whole matter of stabilizing money out of the hands of the politicians and the speculators, insofar as both classes are to their own profit making use of instability and proffered remedies. That is, Mr. McCullough would have the voters see to it that their representatives in Congress enact legislation for the Fisher plan, or some other plan that would substitute a stable for a "dancing dollar."

The vital importance of the subject and the brevity and clarity of the treatment make the volume deserve a wide reading while the fact that the author is an engineer should give it particular interest to members of the engineering profession.

New Treatise on City Pavements

CITY PAVEMENTS—By F. S. Besson, Major, Corps of Engineers, U. S. Army; Assistant Engineer Commission, District of Columbia. New York and London: McGraw-Hill Book Co. Cloth: 6 x 9 in.; pp. 421; 199 line cuts and halftones. \$5.

A quite different line of approach to a discussion of city pavements has to be pursued today than was followed in the older familiar treatises on pavements. Paving materials and pavement construction are still important factors, but the problem of paving a city has been made much more complex by questions of street-system planning, zoning of streets, and weight and volume of traffic. This changed situation is exemplified well in the most recent of treatises on city pavements by Major Besson. Of the 400 pages 100 discuss organization, records, contract practice, street systems, pavement selection, and detail design. It is in these first 100 pages that the engineer old in the service of city street departments will find his greatest inspiration.

Of the three other major divisions of the book one is devoted to bituminous pavements and one to block pavements and the third to concrete, which is the base for both bituminous and block surfaces. In each of these three divisions the plan of presentation, in from four to seven chapters, is (1) materials and tests; (2) design of mixtures; (3) construction plants and methods. Generally the requirements of the American Society for Testing Materials in respect to materials and tests are followed by the author. In discussing concrete mixtures the modern theories of proportioning by fineness modulus and surface area are given along with the methods by voids and proportioning by tables. This chapter on the design of concrete mixtures and that on the design of bituminous mixtures are among the most useful portions of the volume.

Altogether, however, the city paving engineer will get most of value from the sections on administration and management and on planning and design. Major Besson favors a military organization in street administration and emphasizes the use of plans and records. These include topographic, highway-plan and work-progress maps; street, alley and measurement sheets; maps, cost and traffic records. Contracts are fully discussed and

the chapters on street systems, selection of pavements and street and pavement design are notable contributions to the information available to the street and pavement engineer.

Highway Motor Transportation

MOTOR TRANSPORTATION OF MERCHANDISE AND PASSENGERS—By Percival White, Research Engineer; Formerly Manufacturer of Projecta Cars, London, England; Director of Development, Aluminum Manufacturers, Inc., Cleveland, Ohio; and Ordnance Expert, War Department; M. Am. Soc. M. E. Soc. Automotive E. etc. New York and London: McGraw-Hill Book Co. Cloth; 6x9 in.; pp. 486; illustrated, \$4.

Highway engineers have need of a general treatise on motor transportation, which it has been the purpose of the author of this to produce, rather than of manuals discussing in more detail single phases of the subject. No engineer of highways is today in a position to plan broadly and to design efficiently without a general knowledge of traffic, of the vehicles which act on the highways and are reacted on, and of transport relations and development, but he does not want details which concern only the automotive engineer or the bus-line manager. Naturally the text is directed more particularly to the manager of motor transportation than to the highway engineer, but even in the discussion of transport problems, specifically, as vehicle design and maintenance, operating organization, routing and scheduling traffic, accounting and insurance, the treatment has, because of the extent of the subject, to be confined to presenting general principles and conclusions which hold interest to the highway engineer.

In presenting his discussion the author aids the reader by an introductory chapter in which are described the outstanding aspects of motor transport which are considered in detail in the succeeding chapters, and by outlines heading each chapter. Both were found by the reviewer a distinct aid in visualizing the plan and contents of the volume and in co-ordinating his ideas later in the more careful reading of the several chapters.

Of the twenty-seven chapters, five relate to the design and maintenance of vehicles, eleven to such fields of freight and passenger service as express haulage, bus operation, etc., and the others to general questions of administration, operation and accounting. Highway engineers will be particularly interested in the chapters on the truck and the railroad, on truck legislation, and on insurance. It is, however, as a general picture of highway motor transportation which the highway engineer needs to visualize that the volume offers most of value.

Trade Associations Explained

TRADE ASSOCIATION ACTIVITIES—Prepared by L. E. Warford and Richard A. May Under the Direction of Julius Klein, Director, Bureau of Foreign and Domestic Commerce, Washington: Superintendent of Documents. Paper; 6x9 in.; pp. 268. 59c.

Much has been heard about the trade association in the past few years. Owing to the inquisitive notice of them taken by the Department of Justice and the condemnatory mention several of them have had by the United States courts, they cannot be said to be very much in favor at the present time. It is a fact, though, as Secretary Hoover says in the preface to this government report on such associations, that their "constructive purposes unfortunately have been confused with the minority of activities which have been used as a cloak for action against the public interest."

The report is, therefore, a welcome corrective. It is intended, according to Mr. Hoover, "to present a picture of the organization, administration and operations of trade associations with a view to meeting the need for public information on the subject and, further, in order that a business facility which is economically useful, when properly conducted, may not suffer discrimination by reason of misapprehensions regarding its purposes and accomplishments." It contains, in addition to the introduction, which outlines the problems and the activities of trade associations, chapters written by various specialists on statistics, legislative activities, standardization, accounting, trade disputes and ethics, employee and public relations, insurance, public relations, traffic and transportation and research. There are, in addition, chapters explanatory of the functions of the government in assisting trade and a suggested form of organization for associations. Appendices contain some historical notes and a directory of such associations as now exist.

The book is the result of an investigation undertaken jointly by the Bureau of the Census, Bureau of Foreign and Domestic Commerce and the Bureau of Standards. It was guided and supervised by a committee headed by F. M. Feiker. Among the other members of the committee were: E. W. McCullough, Chamber of Commerce of the United States; S. L. Nicholson, Electrical Manufacturers' Council; Alfred Reeves, National Automobile Chamber of Commerce; and Nathan B. Williams, National Association of Manufacturers. L. E. Warford was secretary of the committee.

Pioneer British Regional Planning Work

THE DONCASTER REGIONAL PLANNING SCHEME: Report Prepared for the Joint Committee by Patrick Abercrombie, University of Liverpool, and T. H. Johnson, Doncaster. Together with an Appendix on Coal Subsidence by Joseph Humble, Doncaster. London: Hodder & Stoughton, Ltd., for the University Press of Liverpool. Paper; 10 x 12 in.; pp. 93; plates of half tones and maps and colored folding maps. 10s. net.

City planners in America and elsewhere who have been engaged of late in promotional or actual regional planning work will find this report interesting and suggestive. It deals with a part of England that only of late has begun to change from a rural area with Doncaster as its center and a few scattered hamlets and villages to what promises to be a hustling mining and manufacturing district. Doncaster and possibly some of the smaller places have not only begun town planning but have also had the vision and initiative to take up regional planning as well.

Doncaster and other local authorities in the new coal-fields district near Sheffield and Leeds, England, on being convened by the Ministry of Health in January, 1920, to consider industrial development in that section, formed a joint town-planning committee composed finally of representatives of nine local government areas. This committee, with the clerks and the surveyors of the several communities, and with the aid of the specialists named above, have produced what Prof. Abercrombie in his Introduction describes as the "first regional planning scheme to be prepared," presumably meaning in England. Reference is made to the South Wales Regional Survey noticed in these columns, Nov. 16, 1922, p. 850, as a demonstration of the need of a plan.

Zoning along unique lines following topography and taking into account land subsidence and other problems incident to a colliery region is a notable feature of the

regional planning scheme. The committee outlines a plan, having as its "general aim" a dozen "self contained and well-defined towns" with Doncaster as the "capital town" and with the intervening areas given up to "agricultural land, small holdings, allotments and playing fields." Three zones are proposed: (1) Industrial, comprising certain low-lying lands; (2) agricultural or industrial, with prohibition of new dwellings "except what are absolutely essential for local agricultural purposes, this zone to comprise land below the 25-30-ft. contour, the exact line to vary with local conditions; (3) a neutral zone, above the 25-30-ft. contour, usable for either housing, commerce or clean industry . . . well-balanced communities being planned as the type of suitable local development becomes apparent." Maximum building heights of 76 ft. for all but the industrial zone are proposed, but with no part of any building projecting "above a line drawn from the center of the street in front at angle of 56 deg. with the horizontal."

Other subjects covered by the report are preservation of certain villages, places of natural beauty and of ruins; road widenings and extensions, including much-needed ring roads, and the fixing of building lines; better railway facilities as regards local traffic (the district already has a notable system of through railway lines, as it has also through highways); improvements of the three waterways of the district; also the provision of civic centers and of regional parks.

The suggestions for regional parks show a timidity that seems to be only partly excused by uncertainty as to the location and needs of future development and the general lack of areas which thrust themselves forward for being set aside because of their eminent fitness as parks and reservations.

From the viewpoint of present-day knowledge of the origin and control of diphtheria one sentence in the report seems inexcusable. In this sentence it is stated that a health survey of the Doncaster region "would probably show that in certain villages in the flood lands such terrible diseases as diphtheria may be said to be endemic." This is incidental and immaterial, so far the main purposes of the report are concerned, but the appearance and usefulness of the many regional plan inserts is damaged by failure to letter the originals for reproduction. The result is that without a magnifying glass most of the lettering on these maps cannot be read. The same is true of the names of minor places on the large colored folding maps at the back of the report.

Finally, the Doncaster regional plan is a commendable piece of work. The report will repay study by city and regional planners everywhere.

PUBLICATIONS RECEIVED

Notes on Pamphlets and Reports

EXCELLENT PAPERS BY LEADING HIGHWAY ENGINEERS are given appropriate dress in the well-edited and handsomely-printed Proceedings of the 1923 convention of the American Road Builders Association. Too commonly the technical society report is a poor example of book-making with little if any editing beyond the clerical process of assembling the material in order of presentation at the convention and correcting the most obvious errors of the convention stenog-

rapher. It is in being the direct opposite of these things that this report deserves study by association secretaries and publication committees. It is edited as a high-class technical journal or a scientific book is edited and typography and illustrations are co-ordinate elements of the editorial plan. It is bound and printed in the manner of the better-class engineering books. It is a credit to the growing organization which publishes it.

RARELY DOES A TECHNICAL SOCIETY publish its convention proceedings within less than two months of the date of its meeting, as has the National Conference on City Planning this year. The meeting closed on May 2; the *Proceedings* were out by June 20. (Flavell Shurtleff, secretary, 130 E. 22nd St., New York City; \$2.25.)

NEARLY A MILLION TRADE UNION MEMBERS (actually 861,893) are covered in the eleventh annual bulletin of the Bureau of Labor Statistics on Union Scale of Wages and Hours of Labor, May 15, 1922. Figures are given for 66 of the chief cities of the United States, with comparative figures for May 15, 1921, and with summaries by trades going back to 1907. In view of the importance of this and related labor and industrial problems it is a pity that these figures are a year old on publication.

IT PAYS TO GIVE VACATIONS WITH PAY to both office and factory employees according to conclusions drawn from data given in "Employee Vacation Plans." Reports from many manufacturing, commercial, financial and other concerns are briefed separately and 121 vacation plans for (1) executive and office forces and (2) factory employees are summarized in two small tables. (Boston, Mass.: Bloomfield & Bloomfield, Consultants in Industrial Relations; \$1.50.)

AIRWAYS AND LANDING FACILITIES are the subject of a 112-p. illustrated pamphlet recently prepared by the Office of Chief of Air Service, Washington, D. C. While the information is primarily for pilots of air craft some portions of the text are of interest to engineers, particularly those relating to the location, size and construction of air terminals and landing fields. The circular contains a list, by states, of landing facilities throughout the country.

THE POPULATIONS OF the 542 incorporated cities of Kansas and the officials of 514 of the cities, together with lists of the 11 cities having managers and the 46 cities under commission government are given in Bulletin 41 of the League of Kansas Municipalities. (Lawrence, Kan.; \$1.)

PUBLIC UTILITY RATES FOR 542 KANSAS CITIES, as of Jan. 1, 1923, contains quite a bit of other information regarding 255 municipally- and 6 privately-owned waterworks; 237 public and 179 private electric plants; 7 public and 109 private gas works and 590 telephone stations. (Lawrence, Kan.: League of Kansas Municipalities; \$2.50.)

REHABILITATION OF THE NEW ENGLAND RAILROADS and the operation of them as a regional system is proposed by report of the Joint New England Railroad Committee to the Governors of the New England states, as preferable to consolidation with one or more of the large eastern systems. An abstract of this report appears elsewhere in this issue.

IRON AND STEEL STATISTICS, 1919-21, for the British Empire and Foreign Countries and copper statistics likewise are available in pamphlet form. (London: His Majesty's Stationary Office; 11s. and 3s. net.)

A SPOT MAP OF THE 312 CITIES in the United States and Canada known to have city managers is a feature of the 1923 Year Book of the City Manager's Association (Lawrence, Kan.: John G. Stutz, secretary; 50c.).

VESTNIK PRO VODNI HOSPODARSTVI (Review of Water Economy) is the name of a periodical issued by the government of Czechoslovakia. Similar publications from other countries are desired by the editor, Ing. Josef Vrba, secretary, Ministry of Education and private professor at the Czech School of Technology, Prague.

STATISTICS OF INCOME for the calendar year 1921 have just been issued by the Commissioner of Internal Revenue

(Washington, D. C.) as a preliminary pamphlet report devoted to personal income tax returns alone. It has some very interesting information regarding distribution of income by classes and localities.

A MONOGRAPH ON EXPLOSIVES designed to meet the lack of a comprehensive work on the subject has been issued by the Bureau of Mines. The authors are C. A. Taylor and W. H. Rinkenbach and the title is *Explosives: Their Materials, Constitution, and Analysis*. (Washington, D. C.; pp. 185; one copy free; additional copies 20c. from Superintendent of Documents.

RECONNAISSANCE AND SIGNAL BUILDING, by Jasper S. Bilby, Signalman, U. S. Coast & Geodetic Survey, supplies "information on a subject not fully treated in any previous manual of the U.S.C. & G.S." (30c. from Superintendent of Documents, Washington, D. C.)

CONFERENCES ON SEWAGE TREATMENT have been held annually for four years at Iowa State College, Ames, Iowa, under the auspices of the Engineering Extension Department. Among the six papers read at the 1922 conference and now available as a department bulletin, are *The Role of Bacteria in Sewage Purification*, by Prof. Max Levine, and *The Activated-Sludge Process*, by Prof. Edward Bartow.

OUR LUMBER PRODUCTION DECLINE is strikingly shown in the *Lumber Cut of the United States, 1870-1920*, by R. V. Reynolds, Forest Examiner, and Albert H. Pierson, Statistician, in Forest Products, U. S. Forest Service (pp. 63; illustrated). The cut for 1920 was 27 per cent below the peak production of 1907, and 2.2 per cent below the 1919 cut.

ZONING IS RECEIVING SO MUCH ATTENTION just now as to make two new pamphlets on the subject welcome. In *Present Attitude of Courts Toward Zoning*, Edward M. Bassett, Counsel, Zoning Committee, New York City, presents a review that would be useful wherever zoning ordinances are being framed or in litigation. *Regional Zoning*, by Robert Whitten, city planner, Cleveland, Ohio, reviews the extension of zoning to whole districts. (National Conference on City Planning, 130 E. 22nd St., New York City.)

New Books and Revised Editions

ACOUSTICS OF BUILDINGS: Including Acoustics of Auditoriums and Soundproofing of Rooms—By F. R. Watson, Professor of Experimental Physics, University of Illinois. New York: John Wiley & Sons, London: Chapman & Hall, Ltd. Cloth; 6x3 in.; pp. 155; 72 line cuts and halftones. \$3.

CARATTERISTICHE COSTRUTTIVE DELLE TURBINE IDRAULICHE Negl' Impianti Attuali—By Ing. Guido Gambardella, Milan, Italy; Antonio Vallardi. Paper; pp. 133; 17 line cuts.

According to the author's preface, this is not a textbook but rather an attempt to connect recent theory with current practice, showing the relation of recent studies and laboratory tests to methods of construction and installation in use in Europe and America. It is intended to be a guide for students as to the theories now actually put into practice; and for manufacturers in selecting the type of turbine best suited to their needs.

CROWELL'S DICTIONARY OF BUSINESS AND FINANCE—New York: Thomas Y. Crowell Co. Cloth; 6x9 in.; pp. 605. \$3; postage extra.

Definitions, mostly short, of thousands of words and expressions current in business and finance and associated law.

FOUNDATIONS, ABUTMENTS AND FOOTINGS—Compiled by a Staff of Specialists; Editors-in-Chief; George A. Hool, S.B., Consulting Engineer, Professor of Structural Engineering, University of Wisconsin, and W. S. Kinn, Professor of Structural Engineering, University of Wisconsin. Assisted by Horace S. Baker, S.B., Chief Engineer, Frank D. Chase, Inc., Chicago. New York and London: McGraw-Hill Co., Inc. Cloth; 6x9 in.; pp. 414; illustrated. \$4.

PRACTICAL RAILWAY MAINTENANCE—By Charles Weiss, C.E. New York and London: McGraw-Hill Co. Cloth; 6x9 in.; pp. 349; illustrations and tables. \$3.50.

THE DESIGN OF STEAM BOILERS AND PRESSURE VESSELS—By George B. Haven, S.B., Professor of Machine Design, Massachusetts Institute of Technology, and George W. Swett, S.B., Associate Professor of Machine Design, Massachusetts Institute of Technology. Second Edition, Revised. New York: John Wiley & Sons, Inc. London: Chapman & Hall, Limited. Cloth; 6x9 in.; pp. 435; 206 illustrations. \$4.

Nineteen pages of text and six illustrations have been added to the present edition. There is a new chapter on "the logical design of a water-tube boiler." The first edition was favorably reviewed by William H. Boehm, of the Fidelity & Casualty Co., in *Engineering News*, June 15, 1916, p. 1135.

Bronx River Bridge Abutment Held by Girder Brackets

By ARTHUR G. HAYDEN

Senior Assistant Engineer, Bronx Parkway Commission, Bronxville, N. Y.

THE May 31 issue of *Engineering News-Record* reports on p. 971 the use of brackets on a deck plate-girder bridge of 34-ft. span near Vienna, Austria, to prevent the overturning of yielding abutments. It may be interesting to know that the same device was used on a Bronx Parkway bridge two years before the Austrian example.

Development of the parkway necessitated moving the channel of the Bronx River in the vicinity of the New York Central R.R. station at Mount Vernon, N. Y., westward about 60 ft. Sherwood Ave. Bridge crosses

GIRDER BRACKET TO HOLD ABUTMENT

the river at this point, and the bridge was moved west to span the new channel. The old east abutment was abandoned and the old west abutment was used as the east abutment (Abutment B) of the relocated bridge, a new west abutment being built. The new river channel was excavated back of Abutment B, and the old channel filled in front of it.

It is thus seen that the direction of the earth thrust on the abutment was reversed, and the abutment was not safe for this condition. The resultant pressure line, including the bridge reaction, came near the edge of the base. Addition to the abutment to increase its stability would have been expensive and unsightly. Therefore the scheme was devised of supporting the abutment against overturning by means of brackets attached to the bottom flanges of the girders.

The brackets were adjusted with slight clearance at high temperature, so as to avoid temperature stresses in the girders due to expansion. Thus, no load will be imposed on the girders unless the abutment actually yields. If this does occur, the abutment will be braced against the new west abutment by means of the brackets at either end of the girders. Calculation shows that the maximum possible load from the brackets might reverse the dead- and live-load stresses in the girders near end of span, but would not exceed safe limits.

Sherwood Ave. Bridge is a four-girder bridge of 55-ft. span with concrete floor, and carries a 32-ft. roadway and two 7½-ft. sidewalks.

Letters to the Editor

This department aims to be a forum for the discussion of the views of engineers and contractors. The range of interest should be as wide as possible. Contributors are, therefore, asked to make their letters short.

Building Height Restriction

Sir—In your issue of July 12, 1923, p. 45, you attempt to discuss "Building Height Uncertainties." Evidently the writer of the editorial has been Rip Van Winking in municipal affairs for several years past.

He admits that "half a dozen cities have concerned themselves with the question in recent months." Ten times that number would be more accurate. Any city or village that takes up the question of zoning in a comprehensive way must consider height regulation. There are now 145 municipalities of all sizes in this country that have adopted zoning ordinances and nearly that many others have zoning under consideration.

It is hard for a New Yorker to believe, but in that vast unknown territory stretching west from the Hudson River there are quite a number of people. They are not all Indians, either. About a thousand miles west of the metropolis there is a place called Chicago that is nearly half as big as New York. Thirty years ago that village started to regulate the height of its buildings and is still doing it.

"Nowhere, however, has substantial reasoning been brought to bear on the problem. So far as can be judged, esthetic notions are leading factors in the discussion." Rot! If you are to write more for the edification of those interested in municipal problems, you should read up. As a starter on "Heights" read "Studies on Building Height Limitations in Large Cities," by The Chicago Real Estate Board.

A. H. C. SHAW,

Engineer, City Planning Commission.
Columbus, Ohio, July 14, 1923.

Backfilling to Avoid Settlement

Sir—It has been the practice of contractors, corporations, and plumbers, who have occasion to open streets, to place the backfill in such a manner as to cause a mound of earth over the opening, which after a few rains generally sinks into a deep depression, leaving holes in paved streets, which remain in bad condition for a long period of time, causing great inconvenience in the use of the highway, breaking automobile springs and causing accidents.

In order to avoid these conditions, the following procedure, which has been followed by the Office of the President of Manhattan of the City of New York for the past eight years, is recommended.

It is reasonable and advisable to hold the one who makes the opening responsible for its backfilling in such a manner as to avoid settlement. This is the basis of the system proposed. It is accomplished by requiring the contractor, plumber, or corporation who makes an opening to guarantee that there shall occur no settlement in the refilled opening for six months after backfilling. In contracts with the city sufficient money is held back for six months to cover the cost of repaving if it should become necessary. Corporations are required to furnish bonds, and are charged twice in case the repaving of the filled opening becomes necessary within six months. Plumbers are required to deposit a sum equal to twice the estimated cost of repaving. This money is held for six months, and if the filled area is required to be repaved a second time, the work is done by the city and charged against the plumber. If, however, his fill has been made so well that no settlement occurs after six months, he is refunded the balance of his deposit.

Each permittee who opens a street has a financial in-

terest in backfilling in such a manner as to avoid settlement. Eight years' experience in the Borough of Manhattan has demonstrated that by this simple means the backfill is generally done with proper care, and a great saving to permittee and the public generally is effected.

When it becomes necessary to open a public street, application is made at the office of the President of the Borough or the Public Works Office of a city for a permit. An application blank is furnished which contains a statement of the conditions under which the permit is granted, and clearly sets forth the conditions with reference to backfill and double payment therefor. Separate forms are used for corporations and for general permittees.

Upon filing the application the permittee is required to make a deposit of twice the estimated cost of paying the opening. This has been estimated in Manhattan as follows:

Opening for water in sheet asphalt	16 sq. yd. @ \$5.00	\$1 for permit	\$81.00
Opening for sewer in sheet asphalt	24 sq. yd. @ 5.00	1 for permit	121.00
Opening for water in wood block	16 sq. yd. @ 6.00	1 for permit	97.00
Opening for sewer in wood block	24 sq. yd. @ 6.00	1 for permit	145.00
Opening for water in granite on concrete	16 sq. yd. @ 3.60	1 for permit	58.60
Opening for sewer in granite on concrete	24 sq. yd. @ 3.60	1 for permit	87.40
Opening for water in granite on sand	16 sq. yd. @ 1.00	1 for permit	17.00
Opening for sewer in granite on sand	24 sq. yd. @ 1.00	1 for permit	25.00
Opening for water in macadam	16 sq. yd. @ 2.00	1 for permit	33.00
Opening for sewer in macadam	24 sq. yd. @ 2.00	1 for permit	49.00

At the time the permit is issued, a report is made up on a special form.

To introduce this system into any other municipality the area will be divided into inspection districts. In Manhattan the districts are such that each inspector is enabled to cover every street in his district at least once a week. A portion of the permit report goes to the district inspector, and the remainder is filed at the office as a tickler. The form contains a page for a preliminary report, and one for a final report, which is made six months after the pavement has been first replaced. Upon this report is based the refund to the permittee. The conditions agreed to by the permittee require that the pavement be replaced within 64 hours after notice by the inspector that the backfill has been completed. In highway contracts that provide for maintenance, a clause is included which provides that cuts must be refilled by the contractor at a stated price within 64 hours after notice by the Commissioner of Public Works of the Borough. When the pavement is replaced by the contractor under the maintenance clause, the report of the area is made by the district inspector, and the permittee is charged with the contract price, plus the cost of the inspection. Where the replacement is made by the city force, record of the actual cost is noted and turned in by the inspector on special forms provided. In these reports the quantities of material used, the labor, and the area repaved is recorded, and forms the basis for the charge against the permittee in a ledger account which is kept in a daily permit ledger which is arranged according to the permit numbers, and gives the exact charges and credits against the permit until entirely satisfied after each six months' replacement. This ledger shows the cost of the original replacement, and any additional costs for an additional replacement, as well as the sum deposited by the permittee. The balance due the permittee is also recorded, and the sum he is allowed to liquidate by application to the Comptroller upon certification of the Commissioner of Public Works that the account is ready for liquidation, having passed final inspection, is the balance shown upon this ledger.

By the tickler system, at the expiration of six months the inspector is notified to report upon the condition of the opening which report is made upon a special form.

The application of this system depends upon frequent and efficient inspection, without which it would fail. It is believed, however, to be as good a system as can be recommended, if strictly enforced, and is applicable to any city where the one who makes a street opening is required to pay the cost of repaving the opening.

LOUIS B. MANHEIMER

Assistant Engineer, City Planning Bureau,
Borough of Queens, City of New York

Long Island City, N. Y.,
July 1, 1923.

How to Get Apprentices

Sir—Your editorial "Who Restricts Apprentices?" in the issue of July 12, 1923, p. 45, is very much to the point. It directly touches a point familiar to all interested in building work from its many angles. The condition in New York certainly must be typical of the general condition throughout the country.

It is not possible for one man to find or fix a cure for the existing condition. However, if a sufficient number of people throughout the country would think about this condition and then act, first by publishing their opinions, then by following their publications by co-operative action, some definite results could be obtained. For instance, in our local territory, and we serve in and throughout Maryland, parts of Pennsylvania and West Virginia, the lack of apprentices in the various trades cannot be blamed entirely upon unions or contractors or that portion of the younger generation from which apprentices are usually drawn, but all are responsible. It would be foolish to claim that union rules control the number of apprentices when there are not sufficient apprentices to fill the vacancies which are at present in existence.

Take the situation in our own city of Cumberland, there are no apprentices available for the bricklayers' trade, we know of no apprentices in the plasterers' trades, and so it goes throughout all of the various building trades. It would be foolish to blame the lack of apprentices on the contractors of this city because there is sufficient co-operation between contractors and the various unions to insure completion of any job and incidentally to insure placing of any available apprentices. Also the contractors would be cutting their own throats if they did not endeavor to bring prospective apprentices to the notice of the various unions.

It will be recognized as a fact that the young people of the present age are more interested in dancing and white-collar jobs, so-called, than they are in such work as bricklaying or any other mechanical trade. In every college there are students trying to be lawyers, architects, or other professional students who could better be plumbers, bricklayers or mechanics. If every college were fitted with a mechanics or trades department a portion at least of these students who find they are fitted for a mechanical line or discover their ambition while students could very readily take up their choice of studies in the college in which they are entered. Then, too, the proper incentive of a large percentage would be put before them at a time when it would do the most good. Many young men who start out in life experience several changes of vocation in the first four years of business life. This, of course, does not hurt them but gives a valuable knowledge of men and conditions. It only delays the individual in the finding of a proper and suitable vocation for which he is most suited. This thought was confirmed by a recent editorial in your paper wherein it was stated that a large number of men were going back to or into the trades.

It seems, therefore, to be up to all concerned to encourage the mechanically inclined to choose a trade at an early day in life. If all of the boys graduating from technical or mechanical, engineering or architectural, courses would serve from three to four years in any one of the building trades before taking up their engineering vocation, the need for apprentices would constantly be met and these young men would then have a practical and efficient foundation for their chosen vocation in their respective professions.

The answer to "Why is a student?" is probably that said student desires or has the ambition to get above the other fellows and so studies for a number of years to get himself there by the quickest road, but the true student is a life student and therefore four years spent in practical work in any trade would not be a handicap, and incidentally the average mechanic now commands more during his apprenticeship than the average engineer in the first year of his career. The worthy apprentice will eventually rise above the trade, especially those who have been through a higher college and obtained a degree, and all of them will

be more efficient and capable for the experience gained during their apprenticeship.

J. B. BROWER, JR.,
Cumberland, Md., July 14, 1923. Architect.

High Cost of Detours

Sir—High cost of detours in constructing roads in Wisconsin is analyzed in an impressive manner by N. M. Isabella in your issue of June 21, p. 1088. The subject is one to which very inadequate attention has thus far been given and it is to be hoped that Mr. Isabella's presentation and your editorial comment will go far toward giving the subject its proper place in the economics of road construction.

Mr. Isabella's estimates are quite conservative; in fact too conservative. He makes no estimate as to the cost of maintaining detours in passable condition or as to the increased cost of operating the motor vehicle over detours due to bad grades and unsatisfactory road surfaces. These items would undoubtedly swell the total considerably to say nothing of the time loss and annoyance to users.

In suggesting the methods of reducing the penalty imposed upon the traveling public Mr. Isabella entirely omits the one mathematically certain method of reducing the detour period, namely, that of changing the type of construction from portland cement concrete to a type which does not have to be shut off from traffic while it is curing. As stated by Mr. Isabella fourteen days are required for this curing process in Wisconsin and in some other states as high as twenty-one days are required for this purpose. Asphaltic concrete on the other hand may be thrown open to traffic upon its completion. Fourteen days cut from the 81.6 days average mentioned by Mr. Isabella would result in a saving of \$630,000 and if there is any merit to my statement that additional costs are involved in the maintenance of the detours, in the increased operating cost of the motor vehicle and in the lost time by the road users it may reasonably be stated that the substitution of asphaltic concrete pavements would result in a saving of \$1,000,000 in the item of detours alone. What is true of Wisconsin is true of any other state and it must be quite evident that the detour penalty we are placing upon our traffic throughout the United States runs far up into the millions of dollars.

If the asphaltic concrete type of pavement were experimental I should not make the suggestion that it be considered. It is a matter of service record that this type of pavement has been in use for upwards of forty years. In the City of Visalia, California, is a pavement of this type laid in 1894 which has cost nothing for maintenance and is now in excellent condition. Millions of yards of this type have been laid on the Pacific Coast and while it has not been extensively used in the East, remarkable results have been obtained where it has been laid. In Erie, Pennsylvania, a section which had been down over thirty years and which was in good condition was recently taken up on account of changes in underground service.

Because of its flexibility and its water-resistant quality the asphaltic concrete pavement is seldom laid to a total of more than 6 in. The usual thickness is 5 in. made up of 3-in. base and 2-in. asphaltic concrete top or 3½-in. asphaltic concrete base and 1½-in. sheet asphalt top. Where the subgrade is of a water holding soil it is customary to lay a course of 3 or 4 in. of broken stone. This would be desirable on some of Wisconsin's roads but on the whole it should be possible to adapt this admirable type to the Wisconsin program with little increase in the construction costs.

Apart, however, from the merits of the asphaltic or portland cement concrete types of pavement it can scarcely be contested that the item of detour costs should certainly be taken into account in the selection of a type of pavement rather than to be considered after it is too late to weigh it as an economic factor in the selection of type.

I make the foregoing suggestion not in a spirit of criticism of the portland cement concrete type of pavement but because I believe the highway engineering profession and the tax-paying public will profit by a discussion which will bring out the economics involved in this phase of road construction.

J. E. PENNYBACKER,
New York, July 3. Secretary, Asphalt Association.

News of the Week

CURRENT EVENTS IN THE CIVIL ENGINEERING AND CONTRACTING FIELDS

News Brevities

The Public Service Corp. of Quebec has announced that the name of the Quebec Railway, Light, Heat & Power Co. will be changed to the Quebec Power Co., and its capital increased from \$3,000,000 to \$10,000,000. No information is at present available as to why this increase in capital is being made.

Judgment of \$161,187.31 to the C. S. Lambie Co., engineering and contracting firm, Denver, Colo., has been granted as money due on contract for the large reinforced-concrete building erected by Lambie for the L. R. Steel Co., the company going into the hands of a receiver about the same time that the building was completed.

A preliminary permit and license to develop 360,000 hp. on the Susquehanna River near Conowingo, Md., has been granted to the Susquehanna Power Co. by the Federal Power Commission. The preliminary permit gives the company priority over other interests which might seek rights to develop this power. If the final permit is approved the development, which calls for an expenditure of approximately \$30,000,000, will be started at once.

The Milwaukee Harbor-Rail Committee was organized by the Milwaukee Harbor Commission on the recommendation of the Milwaukee chapter of the American Association of Engineers, not at the request of the Milwaukee Society of Engineers as stated in *Engineering News-Record* May 31, 1923. J. A. B. Tompkins, representing the Harbor Commission as its consulting engineer, is chairman of the committee.

The Hudson & Manhattan Railroad Co., has declared its first half-yearly dividend of 2½ per cent on its preferred stock. This railroad which operates two tubes under the Hudson River between New York and New Jersey was constructed at an average cost of \$3,500,000 a mile. Recent large increases in the passenger traffic and an increase in fares granted by the Interstate Commerce Commission are responsible for this improvement in the railroad's financial condition.

To Help Relieve Traffic. Conditions in New York City the parked strips in the center of Park Ave. are to be narrowed from 56 to 20 ft. by taking 18 ft. off each side. The narrowing will extend for the eleven blocks from 46th to 57th St. An appropriation of \$1,661,000 for the work was made by the Board of Estimate the latter part of June. The high cost is said to be due to the necessity of carrying supports for the roadway to the track level of the New York Central some 40 ft. below. The sub-surface work will be done by the railway.

Pinchot Vetoes Engineers' License Law Repeal Bill

On July 12 Governor Pinchot of Pennsylvania vetoed the bill passed by the recent session of the Pennsylvania Legislature repealing the engineers' registration and license law.

R. H. Keays Is Chief Engineer of Moffat Tunnel Commission

R. H. Keays has been appointed chief engineer of the Moffat Tunnel Commission; and Major L. D. Blauvelt, state highway chief engineer of Colorado, has been added to the consulting board of the Commission, the other members of which being D. W. Brunton, J. V. Davies, and J. Waldo Smith.

Mr. Keays was assistant general superintendent for the Ulen Contracting Corp. on construction of the Shandaken Tunnel for the Catskill water supply of New York City. He was born in 1874 and is a civil engineer graduate of Cornell University. He spent several years in Porto Rico and Cuba and was, in 1900, in direct charge of the design of the sewer and water systems of Havana. Previous to that he was an instructor in mechanics and hydraulics at Cornell University and engineer on field work on Hydraulic surveys and sewer systems in New York State.

Hirst-Potts Hearing on Trenton Sewage Works July 24

The charges brought against Clyde Potts, an engineer-member of the New Jersey Board of Health, by H. Jerome Hirst, of the Direct-Oxidation Disposal Corp., alleging that Mr. Potts held up the Trenton sewage-works plans because he was refused stock in the company, will be heard by the Board at Trenton, July 24, at 10:30 a.m., daylight-saving time.

Order Restraining Shopmen in Strikes Made Permanent

A sweeping temporary restraining order, affecting 400,000 railroad employees and officers of the shop crafts unions, has been made permanent by the final decree by Judge Wilkerson of the Federal District Court in Chicago. "The significance of the order," says Attorney General Daugherty, "is not its application to the present shopmen's strike, which theoretically is still in existence, but in its effect on future strikes as a matter of precedence. It not only enjoins the strikers from interfering with railroad properties, but also enjoins them from interfering with the railroads' business, from picketing, from parades and meetings, letters, telegrams, telephone messages or any other acts that would interfere with or incite against the operation of the railroads."

Am. Soc. C. E. Protests Removal of A. P. Davis

Convention Adopts Resolutions Against Converting Reclamation Service Into Political Machine

In protest against the summary dismissal of A. P. Davis from the position of director of the U. S. Reclamation Service, the American Society of Civil Engineers at its annual convention in Chicago, July 11, adopted by unanimous vote the following resolution and statement prepared by the Board of Direction.

"Whereas, the director, formerly chief engineer, of the U. S. Reclamation Service, has recently been summarily dismissed by the Secretary of the Interior, apparently without a hearing, after a connection with this Service since its organization over twenty years ago—this Service being a Bureau charged with the construction and operation of engineering works, and

"Whereas, this summary dismissal of the head of a technical bureau, apparently without a hearing, may be made the precedent for other similar removals when prompted by political expediency; and because the engineering profession is deeply concerned in the wise and efficient direction of public works,

"Resolved, That the Board of Direction of the American Society of Civil Engineers approves the action of its executive committee in appointing a special committee to collect additional facts and report further upon this matter."

The Board submitted for the information of the annual convention the following statement:

"The Reclamation Service has had an honorable and a creditable career of over twenty years. Its conduct during that period has been under the constant surveillance of the officers of the national administration, of members of congress and of the residents of the numerous communities in which the projects have been constructed.

"The nature of its operations is such as to arouse the watchful care of those who are to be served and the active opposition of those whose interests might run counter.

SCANDALS LACKING

"Throughout this long period there has been no scandal and no sustained charge of lack of faithful loyalty to public interests. The works erected and the precedents established serve as worthy examples for our own country and have been used as a guide in such developments in other lands. The personnel of the Service has been remarkably loyal, conscientious and devoted to a high standard of public service. The dismissed director has been either chief engineer or director since the establishment of the work in 1902, and was at least entitled to a written statement of reasons for dismissal as provided in civil service regulations, and as required in proper administrative practice.

"The reported reason of better business administration advanced for the replacement of the Director by a successor under the new title of Commissioner, appears to be a pretext which is refuted by the long and honorable business record of the Director dismissed, in comparison with such record as we can obtain of the appointee selected to succeed him. The implication that engineers are not competent business administrators is refuted by numerous engineers who today are conducting as executives, many of the great railroad systems, public utilities and industrial enterprises of this and other countries, and the U. S. Reclamation Service is peculiarly an engineering enterprise.

"The Board fears that any pretext of better administration could only be regarded as a perversion of the proper precepts of a rightful economy to suit the needs of an ever present political situation.

"The Board deplores the action taken by the Secretary of the Interior, for the following reasons:

1. That it will work irreparable injury to the public service in the breakdown of morale and confidence of public employees.

2. That it is an injustice to a man who has given forty-one years of faithful and valuable service to the Government of the United States.

3. That arbitrary methods of removal are not creditable to a popular government based upon equality and fair dealing.

4. That the change now inaugurated bears evidence of an attack upon a worthy and highly creditable branch of the government service to serve political needs.

5. That the conversion of the Reclamation Service into a political machine would result in the withdrawal of public confidence and national financial support with the resultant injurious effect upon the development of the West."

Alabama Power Co. to Build 132,000-Hp. Plant

The new hydro-electric development which the Alabama Power Co. has announced it will build at Cherokee Bluffs on the Tallapoosa River at a cost of about \$10,000,000 will, with the exception of the Muscle Shoals development, be the largest hydro-electric plant in the South. Its ultimate capacity will be 132,000 hp. The initial installation will be two 44,000-hp. units. A dam 800 ft. long, 120 ft. high, and containing 200,000 cu.yd. of concrete will form a reservoir covering 22,500 acres and holding about 25,000,000 cu.ft. of water.

Twenty-five miles of railroad are to be built to give access to the site.

New York Has New Transit Bureau

As a check on the state-controlled Transit Commission the Board of Estimate of New York City has appointed a transit bureau consisting of the dock commissioner as chairman, the president of the Board of Aldermen and the chief engineer of the Board of Estimate.

The new bureau is to handle all negotiations between the city and the Transit Commission.

Robert W. Hunt Dead

Robert Woolston Hunt, head and founder of the nationally known inspection firm bearing his name, died July 11, just one day after the

Board of Direction of the American Society of Civil Engineers had made him an honorary member of the Society. Captain Hunt was born Dec. 9, 1838, in Fallsington, Pa., and spent several years learning the practical side of iron making in the rolling mills of John Burnish & Co., Pottsville, Pa. Later he took a course in analytical chemistry in the laboratory of Booth, Garret & Blair, upon the completion of which he entered the employ of the Cambria Iron Co., Johnstown, Pa., and for them in 1860, established the first laboratory in America as a direct part of an iron or steel organization.

In 1861 he entered the U. S. Military Service and was in command of Camp Curtin at Harrisburg, Pa., with the rank of captain. Upon being mustered out of service he returned to the employ of the Cambria Iron Co. at Wyandotte, Mich., where experiments with the new Bessemer process of making steel were being conducted. He was in charge of the experimental works in 1865, and so continued for a year, when the Cambria Company called him back to Johnstown to take charge of their steel business. It was at this mill later, and largely under Mr. Hunt's direction, that the first commercial order for steel rails ever made in America was rolled.

WITH BESSEMER WORKS

Later he assisted in designing and building the Bessemer works at the Cambria plant, and in 1873 moved to Troy, N. Y., becoming superintendent of the Bessemer works of John A. Griswold & Co. and in 1875 he became general superintendent of the Albany & Rensselaer Iron & Steel Co. During those years of active connection with steel rail manufacture, he almost completely rebuilt the various works of this company, and also patented many details of iron and steel metallurgical processes and machinery, including, in conjunction with others, the first automatic rail mill tables.

In 1888 he removed to Chicago and established the bureau of inspection, tests and consultation, now known as the Robert W. Hunt Co.

Mr. Hunt was twice president of the American Institute of Mining and Metallurgical Engineers; past president of the American Society of Mechanical Engineers; past president of the American Society for Testing Materials and past president of the Western Society of Engineers. He was also a member of various other technical societies both in this country and Europe.

In 1912 he was awarded the John Fritz Medal (for his contributions to the early development of the Bessemer process) and in June of this year he was given the Washington Award of the Western Society of Engineers in recognition of his achievement. He was for many years a trustee of the Rensselaer Polytechnic Institute, and in 1916 received from it the honorary degree of Doctor of Engineering.

Turner Reports on New York Suburban Traffic

Some important features of the suburban traffic problem of New York City and environs are dealt with in the preliminary report on the Metropolitan Transit Plan submitted to the New York City Transit Commission by D. L. Turner, the consulting engineer of that commission. Mr. Turner's study is still in its early stages and no attempt has been made to answer any of the pressing questions of the suburban traffic problem. Some general conclusions are, however, considered practical at this time and are therefore included in his preliminary statement.

The report outlines the area covered in the study, roughly the parts of New York, New Jersey, and Connecticut within a 50-mile radius of the City Hall, estimates its future population, and gives a summary of the present traffic flowing into New York, and a review of the conditions surrounding the passenger service as regards the number of trains per hour during rush hours and the requirements for handling these trains if they were operated in subways in Manhattan.

The report closes with a statement of the following general conclusions: (1) that ten years hence it will be impossible to accommodate the 600,000,000 or more suburban passengers per year with the facilities that now exist; (2) that it will be impossible to take care of this traffic on the city transit lines, for it will be as much as the city can do to obtain facilities for the traffic originating within its limits; (3) that it will be impossible to inject the suburban traffic into the city transit lines by extending them into the territory now served in part by these suburban lines, for under such conditions the trains would be filled to capacity before they reached the city limits; (4) that in order to accommodate this suburban business it will be necessary either to provide additional terminals for accommodating it or to shunt it all past the existing terminals and provide separate and independent collecting and distributing systems traversing central Manhattan, for the exclusive use of the suburbanites now served by the steam railroads; (5) that the second of the two alternatives mentioned above is the proper basis on which to develop the metropolitan transit plan, while adoption of the first alternative would only tend to increase the congestion on the city transit lines, thereby throttling those facilities.

Public Works and Highway Bodies Separated in California

The California Highway Commission was divorced from the Department of Public Works and the state engineer was made head of the latter department by a bill passed by the recent California legislature and immediately signed by the Governor. This action restores the departments involved to independent operation as they were before the passage of the law in 1921 that combined all engineering functions of the state under the Public Works Department and made the state highway engineer head of that department. A report of the combination appeared in *Engineering News-Record* July 28, 1921, p. 167.

Engineering News of the Railroads

Capital Expenditures of the Pennsylvania system for enlargements and improvements in 1922 were restricted to immediate operating necessities, but these expenditures on roadway and structures amounted to \$5,272,483. The annual report states that "much larger expenditures must be made in 1923." The improvements include line revision from Lemoyne to Shippensburg, Pa.; rearrangement of terminal facilities and track elevation at Pittsburgh; classification yard at Sharpsburg; delivery yard at Kearney, N. J.; elimination of grade crossings at Cornwells; shop and engine terminal facilities at Enola, Altoona, Pitcairn and Hagerstown; pier, grain elevator and freight yard at Baltimore; second track and revision of line and grade on Cleveland & Pittsburgh line; construction of low-grade line from Kenwood to Rochester, and track elevation at Indianapolis, Ind.

Completion of Negotiations as to the disposal of the Morris Canal is noted in the annual report of the Lehigh Valley R.R. In March, 1923, the railroad company transferred to the State of New Jersey the ownership of the Morris Canal & Banking Co. and cancelled its lease of the canal property made in 1871. The agreement with the State permanently established the railroad company's title to the "Big Basin" property in Jersey City, on the Hudson River, an important terminal site upon which are piers and other facilities. In addition the company retains the canal right of way through Jersey City and Bayonne, reaching a growing industrial section, and part of the canal right of way at Phillipsburg; but it is relieved of taxes and maintenance of canal property for which it had no use. This means a saving of approximately \$300,000 annually. To secure these favorable terms the company relinquished the balance of the canal right of way, the "Little Basin" on the Hudson River, the water rights of the canal company, and agreed to pay the State \$875,000 in five annual installments.

The Chicago, Indianapolis & Louisville Ry. started work on its track elevation at Indianapolis last year and will continue it during 1923. This will necessitate the construction of a new freighthouse, with team facilities at the street level and tracks and platforms on the upper floor.

The Buffalo, Rochester & Pittsburgh Ry. in 1922 reinstated its policy of general improvement, which had been in abeyance for some years, and will continue the work through the present year. This work includes strengthening steel bridges, replacing timber bridges and trestles with permanent structures and improving the track with heavier rails and stone ballast. The improvements carried out in 1922 included \$170,000 for sidings and yards extensions, \$26,500 for bridges, \$135,280 for rails and ballast, \$53,237 for a coal handling plant at Rikers, Pa., \$44,340 for shop machinery and tools and \$15,014 for the Brown St. subway at Rochester.

The Delaware, Lackawanna & Western R.R. annual report states that a reduced expenditure for additions and betterments in 1922 is "due to the fact that

previous liberal expenditures of this character were for construction of such a permanent value that it was not found necessary to make as great expenditures for these purposes as were required in preceding years."

Improvement Work Now in Progress on the Louisville & Nashville R.R. and expected to be completed in 1924 includes 15.48 miles of second track between Hazard and Lennet, Ky. (with three tunnels paralleling existing tunnels); second track and reduction of grade from Bailey's to Wallsend, Ky., 16.63 miles; and new bridge over the Great Rigolets Pass on the Gulf Coast. New yard facilities at Ravenna, Ky., are expected to be completed in 1923.

The Chicago, Rock Island & Pacific Ry.'s most important item of new work is the double-tracking between Topeka and Herington, 70 miles, about half of which will be completed in 1923. A large capital expenditure will be required by the decision to use oil fuel in Arkansas and Louisiana, but it is stated that the saving in cost of oil as compared with coal will make this a productive expenditure. Studies are being made to convert other divisions to the use of oil. Additions and betterments in 1922 totaled \$2,590,533 for road and \$10,764,747 for equipment.

The Texas & Pacific Ry. is carrying out a program of strengthening embankments and 811 miles were widened to standard width during 1922. Stretches of line were raised and waterways increased 50 per cent on account of floods in the Trinity River valley, while owing to the floods in the lower Mississippi valley during May and June, 1922, a large part of the maintenance forces were engaged in raising and strengthening the levees.

The Chicago Great Western Ry. Reports that it will ultimately acquire the Mason City & Fort Dodge R.R., having made a settlement with the bondholders. The Chicago Great Western Ry. can now go forward with many capital improvements which are needed by the Fort Dodge line but for which there was no provision in the former lease.

Preliminary Work For a New double-track bridge over the Mississippi River, to replace the present bridge at Fort Madison, Iowa, is noted in the annual report of the Atchison, Topeka & Santa Fe Ry. The cost is estimated at \$4,000,000. The report states that this new double-track bridge "is imperatively required by the density of the traffic over the Chicago-Kansas City line and the heavy power necessary to haul it economically." Soundings and preliminary studies for the location of the bridge are now under way.

The Kansas City Southern Ry. Co. Has Been Denied permission to abandon 1.5 miles of its railway into Independence, Mo.

A Steel Side-Wheel Car Transfer Steamer is being built for the New Orleans, Texas & Mexico Ry. for transferring cars across the Mississippi River at Baton Rouge, La. This vessel is 340 ft. long and 91½ ft. wide over the guards, with three tracks, giving a

capacity of eleven large passenger cars or twenty freight cars. The steamer, which is to be put in service this summer, was built by the Dravo Contracting Co., Pittsburgh, Pa., at a cost of about \$255,000.

The Baltimore & Ohio Has Applied to the I.C.C. for authority to abandon 9.3 miles of the Bedford, Md., Branch, claiming that the traffic does not justify the heavy maintenance charges, and for authority to sell 1.5 miles of its line in Bedford to the C. I. & L. Ry. Co.

The Oregon Short Line R.R. Co. Has Applied to the I.C.C. for authority to construct a railroad from Rogerson, Twin Falls County, Idaho, to Wells, Elko County, Nevada, a distance of 98 miles, in order to provide an additional outlet to the highly developed irrigated districts of Southern Idaho.

Authority Has Been Granted to the Southern Pacific R.R. by the I.C.C. to construct a branch line in Kern County, Calif., from Magunden to a point near Arvin, a distance of 17.64 miles. Construction is to begin before July 1, 1923 and be completed by Dec. 31, 1923.

The First Electrically-Operated Train on the Chilean State Railways recently made a successful trip from Santiago to Tiltit and return, a distance of 24 miles. President Alessandri of Chile was at the controller and the American ambassador was a passenger on the train. The order for the equipment for this railway was placed with the Westinghouse Electric & Mfg. Co. in 1921. The total mileage to be electrified is 144.

The Norfolk & Western Ry. lists 130-lb. rails on 115 miles of track and 100-lb. rails on 1,516 miles, of which 70.5 and 221.4 miles were laid in 1922.

Crescoted Ties and 136-lb. Rails are noted in the annual report of the Lehigh Valley R.R. Continued use of treated ties has reduced materially the number of annual renewals, and only 245,848 ties had to be placed during 1922. At the end of the year the railway had 5,953,827 crescoted ties, or more than 64 per cent of the total number, while 415 miles of track were laid with 136-lb. rails.

Valuation on the Erie R.R. is Practically completed and the annual report of the company states that the Bureau of Valuation, Interstate Commerce Commission, has finished for informal review the engineering reports of physical improvements. These reports are being reviewed. Land reports upon the entire system were expected within a few months. The field work was practically finished by the end of 1922 and the entire work about 85 per cent completed. The cost of Federal valuation at the end of 1922 was \$1,143,492, of which \$745,487 was charged to operating expenses, the remaining \$398,005 having been assumed by the U. S. Railroad Administration during the period of Federal control.

A Reduction of 102 Miles in the distance between Toronto and Winnipeg by the Canadian National Railways is being effected by the construction of the 29½-mile Long Lake cut-off, north of Lake Superior, connecting the two main lines of the former Canadian Northern Ry. and National Transcontinental Ry. The contract for grading, bridges and culverts was let in December, and work is reported as progressing favorably. The new line has economic advantages in addition to reducing the mileage.

Random Lines

Thanks for the Ad

Simeon Strunsky, the genial and erudite editor of the New York *Evening Post*, has been traveling into New York over the Long Island Ry. and after the custom of all good editors he has been looking out of the car windows for copy. In consequence, the engineer is indebted to him for the following appreciation:

The deluded archaeologist will write the history of America from the ruins of the Woolworth Tower and the history of Forest Hills from the pink concrete arches of that over-powering railroad station. No one ever excavates market gardens or wheat fields or olive groves. The engineer and the mason hold a corner on history.

The engineer, the mason and the concrete mixer deserve the posthumous credit they are in for, and especially the engineer. He is about the only man who can lift himself by his bootstraps; that is to say, he is the only man who can keep traffic going along an old railroad while he is building a new one. In the region of trans-Jamaica the engineer and the contractor are now engaged in laying new trackage, elevating and depressing roadbeds, throwing lines of shining new railway ties across the ruins of promising park "developments"—and all the time managing to get commuters all into Pennsylvania Terminal and back to their homes almost on schedule; almost, though not quite. The engineer runs his trains over apparently precarious sand piles and around the most casual corners, and the switches grind, and the train halts here and spurts there, and outside the window low-grade Mediterraneans and Alpines in sweat-soaked undershirts dig, and shovel, and heave, and drag, and you get home almost in time—almost, though not quite—and some day there will be a fine new four-track railroad built under your flying wheels.

Perhaps that is what people mean when they want the engineers to tackle the job of world reconstruction. If anybody can somehow manage to keep the old world going while building a new one under its feet it ought to be the engineers.

* * *

A French scientist, returning home from a visit to New York, says that stray electric currents there are undoubtedly affecting the nerve and brain capacity of New Yorkers. There are plenty of Americans who will admit that New Yorkers have nerve, but brains—well, the French were always a polite people.

* * *

The Discussion Was Limited

Everyone who was at Chicago last week seems to agree that the American Society of Civil Engineers' meeting there was a success. And yet—the technical discussion consisted of the presentation of six papers in 2½ hours and ten papers in 3 hours. According to one member, the audience only opened its mouth to yawn.

City of Baltimore Reorganizes Highways Department

The Highways Department of the City of Baltimore has been reorganized under the direction of Bernard L. Crozier, recently appointed highways engineer. Eighteen positions have been abolished and two created, meaning a reduction of \$26,100 in salaries annually. The post of assistant highways engineer, with a salary of \$3,800, is created. It will combine the work of the bridge engineer, department engineer and division engineer of highways. J. Wilson Richardson, bridge engineer, has been appointed to the position. Stuart Purcell, recently appointed chief engineer of Baltimore, formerly filled the position of division engineer of highways. Thomas J. O'Connell was department engineer.

Highway Engineering Fellowships Offered by Michigan

The University of Michigan Graduate School offers again this year according to an announcement by Arthur H. Blanchard, professor of highway engineering and highway transport, the following fellowships: Roy D. Chapin Fellowship in High Transport, Roy D. Chapin Fellowship in Highway Engineering, and Detroit Edison Fellowships in Highway Engineering. Of these, two will be awarded not later than Sept. 10 and two not later than Nov. 1, to holders of Bachelor's degrees from college or university. Each Fellowship carries an allowance of \$300 with no tuition to pay, and leads to the degree of Master of Science or Master of Science in Engineering.

Main Reservoir on Hetch Hetchy Project Fills in Three Weeks

THE siphon spillways in O'Shaughnessy Dam on San Francisco's Hetch Hetchy water supply project began to spill on May 25, three weeks after closure of the valves in the dam. The eighteen siphon spillways each have a capacity of 1,000 sec.-ft. and are built with a 3-in. difference between the throat levels of successive siphons. Thus the capacity of the spillway as a whole will increase as the reservoir level rises. The crest of the dam is at El. 3726½ and the present reservoir level is at El. 3721, at which height the reservoir capacity is 65,000,000,000 gal.

New Phase of Work on Plan for New York and Environs

By Oct. 1 the Committee on the Plan of New York and Its Environs expects to have completed its various preliminary surveys and to begin active planning work. Thomas Adams, the British town planning expert, who has been chairman of the Advisory Planning Group of the committee since Jan. 1, will become general director of plans and surveys on Oct. 1, when Frederic P. Keppel, who has been acting as executive secretary, will retire to become president of the Carnegie Corporation. Frederic A. Delano, formerly president of the Wabash R.R., has already succeeded Charles D. Norton, deceased, as chairman of the committee. Nelson P. Lewis, formerly chief engineer of the New York City Board of Estimate, and other staff members, will continue with the committee.

Rail Committee Against Outside Control of New England Roads

On railroad consolidation as it affects New England the Joint New England Railroad Committee has presented a report to the governors of the six states which is adverse to any consolidation which will turn the railroads of that section over to one of the large trunk lines having its principal interests outside of New England. The committee suggests that New England should run its own roads and with this idea in view it proposes a rehabilitation of the Boston & Maine and the New Haven, state help by the remission of taxes and a guarantee of certain charges, federal aid by a reduction of interest rates, and a sort of trusteeship by men appointed in quotas by the several states. If consolidation with a trunk road is made necessary by legislation or other conditions then the committee recommends that the consolidation be made with the Pennsylvania system.

Colorado River Action May Follow Flaming Gorge Permit Issuance

By granting a preliminary permit to the Utah Power and Light Co. covering its Flaming Gorge project on Green River, the Federal Power Commission has inserted the thin edge of the wedge which is expected to lead to action on the Colorado River projects. Regardless of what Arizona may do with regard to the ratification of the Colorado River compact, it is believed that the Commission will award this fall the Girard license, covering the large development proposed at Diamond Creek. It is believed also that the upstream states could not insist successfully that the Arizona project be held up when they have urged the granting of the Flaming Gorge permit. Prominent officials of both Utah and Colorado now are urging the granting of that permit.

The load of the Utah Power and Light Co. has been increasing at such a rate that a steam auxiliary must be put into operation in the near future. Unless the Flaming Gorge development is allowed to proceed as rapidly as possible, it will be necessary to construct additional steam units. It is to avoid this latter situation that so much pressure has been brought to permit the company to proceed with its foundation explorations at Flaming Gorge.

Engineering Societies

Calendar

Annual Meetings

NEW ENGLAND WATER WORKS ASSOCIATION, Boston, Mass.; Annual Convention, Burlington, Vt., Sept. 18-21, 1923.

AMERICAN PUBLIC HEALTH ASSOCIATION, New York; Annual Meeting, Boston, Oct. 8-11.

AMERICAN SOCIETY OF CIVIL ENGINEERS, New York; Fall Meeting, Richmond, Va., Oct. 15-17.

AMERICAN SOCIETY FOR MUNICIPAL IMPROVEMENTS, St. Petersburg, Fla.; Annual Convention, Atlanta, Ga.; Nov. 12 to 16.

The American Society of Agricultural Engineers will hold its annual meeting in Chicago Nov. 8-10. Principle discussions will include farm power and equipment and farm structures, rural electrification and reclamation, and the problems of teaching and extension and research work. The society's secretary is Richard Olney, St. Joseph, Mich.

The Engineers Club of Baltimore has elected the following officers: president, Earl Stimson; first vice-president, Henry G. Perring; second vice-president, G. J. Regardt, and treasurer, Robert B. Rifenberck.

Personal Notes

F. H. ROOD has been appointed engineer of tests of the Pittsburgh, Pa., Testing Laboratory, with headquarters in Pittsburgh. Mr. Rood is a civil engineer graduate of Syracuse University. For many years he was engineer of tests of the New York state highway commission, for three years he was assistant engineer of tests of the Pittsburgh Testing Laboratory, and for two years a research engineer with the U. S. Bureau of Public Roads.

C. W. CREEKBAUM, recently appointed project engineer on construction for the Florida State Road Department, was formerly county highway engineer of Scioto County, Ohio, and prior to that was assistant city engineer of Portsmouth, Ohio.

A. MCGILLIVRAY, highway commissioner of Manitoba, was elected chairman of the Manitoba branch of the Canadian Institute of Engineers, at the recent annual meeting of the organization.

CARL T. POMEROY, of Melrose Highlands, Mass., for the past nine years health inspector for the North Shore District of the Massachusetts Department of Labor and Industries, became health officer of Montclair, N. J., on July 1, succeeding H. B. Larner, whose services ended Dec. 31 last. Mr. Pomeroy received a C.P.H. from the School of Public Health of Harvard and the M.I.T. a year ago. He was graduated from Bates College with the degree of A.B. in 1909 and soon after-

wards was assistant health officer and bacteriologist at Plainfield, N. J., and then held a similar position at Summit, N. J., each for a short time.

JAMES L. TIGHE, Holyoke, Mass., who for twelve years served as city engineer of Holyoke and since then has been in private practice as a consulting engineer, has been appointed a member of the Public Health Council of the state of Massachusetts.

LEE POWELL, recently of Harris & Powell, highway contractors, has been appointed city engineer of Tyler, Tex., succeeding Sam H. Bothwell, who resigned to become city manager of Longview, Tex. Mr. Powell is a graduate of the engineering college of the University of Texas.

WILLIAM EISENBERG, general contractor, Woodbine and Vineland, N. J., announces the removal of his Vineland office to Camden, N. J.

JOHN DUBUIS and C. M. REDFIELD announce the opening of an office in Bend, Oregon, under the firm name, Dubuis & Redfield, consulting engineers, and will give special attention to irrigation, drainage, water supply, sewerage and hydro-electric work.

ROBERT MCCONNELLY, of Fort Wayne, Ind., has been appointed city engineer of Appleton, Wis., succeeding O. F. Weissgerber, resigned.

P. J. FREEMAN, formerly engineer of tests with the Pittsburgh Testing Laboratory, announces the opening of offices for general consulting engineering at 311 Ross St., Pittsburgh, Pa. He has already been retained by the Standard Inspection Co. to supervise their testing of materials.

DAVID L. STRUTHERS, who has been highway engineer for Gaston County, N. C., with headquarters at Gastonia, has resigned and has been appointed city manager of Gastonia, N. C.

CLEVELAND B. COE has been elected commissioner of public works of Johnson City, Tenn. He is a graduate of Hobart College, was a student at Carnegie Institute of Technology, served as lieutenant of field artillery with the 32nd Division, and since the war has been in private practice in Johnson City.

J. R. ELLIS, assistant chief engineer for the Utah State Road Commission, has resigned to become assistant engineer of the Union Pacific R.R. on construction of the 7-mile line from Park City to the Park-Utah mine.

M. M. LEIGHTON has been appointed chief of the Illinois State Geological Survey, with office at Urbana, Ill., succeeding F. W. DeWolf who resigned recently.

PAUL HAMILTON, engineer of track and roadway on the Cleveland, Cincinnati, Chicago & St. Louis Ry., has been appointed assistant chief engineer, with office at Cincinnati, Ohio, to succeed Hadley Baldwin, who has been promoted.

L. D. SNYDER, civil engineer, who has been a superintendent of construction and specialist in concrete roads and bridges for the George T. Wilhelm Co., contracting engineers, Cedar Rapids, Iowa, has been made general superintendent of construction. He was formerly county engineer at Humboldt, Iowa.

F. E. WEYMOUTH has been appointed a member of the committee to report on the Columbia Basin and Umatilla Irrigation Projects for the U. S. Reclamation Service. The committee now consists of Francis M. Goodwin, Assistant Secretary of the Interior; David W. Davis, Commissioner of Reclamation; and Mr. Weymouth.

ERIC FLEMING, until recently assistant city engineer of New Brunswick, N. J., under Asher Atkinson, city engineer, has resigned to join the architectural and structural division of the Electric Bond and Share Co., New York City.

PAUL C. GISISER, formerly designer for the Southern Power Co., has accepted a similar position with the Fargo Engineering Co., Fargo, N. D.

C. L. CRANDALL has been appointed assistant engineer in charge of surveys for the New York and New Jersey Bridge and Tunnel Commissioners in work on the vehicular tunnel, having served in similar capacity with the Transit Commission of New York City.

ROSS W. TAYLOR has changed from field engineer with A. W. Kutsche & Co., Detroit, Mich., to a similar position with the Otis Steel Co., Cleveland, Ohio.

H. R. SMITH, formerly mayor and city engineer of Belton, Texas, has been made county engineer of Wise County, Texas.

H. D. ROBINSON and D. B. STEINMAN, consulting engineers, have been retained by the West Penn Railways Co. to make an investigation of the suspension bridge across the Ohio River at Steubenville, Ohio, of which a stiffening truss failed under a heavy load as reported in *Engineering News-Record* on May 31. Robinson and Steinman are engaged in making an inspection, recalculation, re-adjustment, and strengthening of the structure for the increased loads it has to carry.

Obituary

SIDNEY B. CADY, Bloomfield, N. J., for thirty years an assistant engineer in the Bureau of Highways, New York City, and later town engineer of Bloomfield, died July 13 at the age of 70. He was a native of Vermont and a graduate of Middlebury College and of Dartmouth.

CHARLES T. TAYLOR, secretary and treasurer of the William Cramp & Sons Ship and Engine Building Co., Philadelphia, Pa., died in that city recently.

WILLIAM DALY, railway contractor, died in Outremont, Province of Quebec, recently at the age of 74 years. He was born in Newton Upper Falls, Mass., and went to Montreal in 1872. He was engaged on the aqueduct intake enlargement, the Lachine Canal, Wellington Basin, and later served the Canadian Pacific Ry. for several years as superintendent of construction.

JAMES T. MCCARTHY, 33 years old, a civil engineer in the employ of the Baltimore & Ohio R.R., died on July 7 at his home in Baltimore. During the war he served as a lieutenant in the Second Engineers.

From the Manufacturer's Point of View

A Point of Contact
Between Maker and User of
Construction Equipment and Materials

Additional Mixer Standards Approved by Committee

Many Details Simplified as
Result of Conference Be-
tween Makers and Users

FOURTEEN provisions for the standardization of concrete mixers were approved by the Joint Committee on Construction Equipment in session with members of the Associated General Contractors and representatives of mixer manufacturers at a meeting held in Chicago, June 27-29. These provisions cover a reduction in the number of types manufactured, the furnishing of auxiliary equipment, standard capacities and ratings and many other points of mutual interest to the manufacturer and the user of equipment. In *Engineering News-Record's* report of the meeting, in its issue of July 5, p. 36, details of about half of the approved measures were given; the remaining points are covered in the paragraphs below:

The recommendations of the Joint Committee, which now go to the Associated General Contractors for approval, deal only with the horizontal non-tilting drum type of mixer. It was recognized that the work of standardizing tilting mixers involved problems peculiar to these types which could only be determined after full consideration of the various points in conjunction with the manufacturers of tilting machines. Another meeting of the Joint Committee is scheduled for this week.

STANDARDS TO BE A.G.C.

Upon recommendation of the manufacturers present at the Chicago meeting it was agreed that the standards adopted should be designated as A.G.C. Standards pending the establishment of contact with the American Engineering Standards Committee and the adoption of American standards. At the request of manufacturers, also, the Joint Committee approved the use of a standard name-plate to be later designed by manufacturers, giving the standard rating of the machine and its capacity for various proportions of mix, with a statement that the machine conforms with standard A.G.C. requirements. As a means of securing general adoption of the recommended standards the manufacturers requested that the right to use the name-plate be obtained from the Associated General Contractors and that the name-plate be purchased through the Joint Committee on Construction Equipment from a company to be designated later.

Portions of the committee's approved report not covered in the issue of this journal referred to in the opening paragraph follow:

For the three standard sizes of paving mixer approved the Joint Committee has prepared Table I, showing the number of sacks of cement per batch.

For three of the four standard sizes

of building mixer, Table II shows the sacks of cement per batch.

BUILDING MIXERS

(a) Extension power loaders shall be eliminated.

(b) Mixers shall be equipped with tanks of sufficient size to deliver the indicated quantities of water per batch as follows: 7-S, 12 gal.; 14-S, 22 gal.; 21-S, 32 gal.; 28-S, 42 gal.; 7-E, 12 gal.; 12-E, 22 gal.; 21-E, 32 gal. Tanks shall withstand a working pressure of 150 lb. per square inch. One tank shall be standard.

Water supply connections shall be furnished as follows: 7-S, 3-in. garden hose nipple; 14-S, 1½-in. standard iron pipe connection; 28-S, 2-in. standard iron pipe connection; 7-E, 1½-in.; and 12-E and 21-E, 2-in. standard iron pipe connection.

TABLE I—PAVING MIXERS

Mix	7-E	12-E	21-E
1-1-3	2	3	6
1-1½-3	2	3	6
1-2-3	2	3	6
1-2½-3	1	3	5
1-2-4	1	3	5
1-2½-5	1	2	4
1-3-6	1	2	4

TABLE II—BUILDING MIXERS

Mix	7-S	14-S	28-S
1-2-4	1	3	6
1-3-6	1	2	4

(c) Discharge control on one side only shall be standard, but may be furnished on both sides as an extra.

(d) Skips shall be made with closed ends.

(e) Standardization of wheels shall be referred to the Concrete Mixer Association for further investigation and report.

(f) Power discharge shall be eliminated as standard but the manufacturers may furnish same on 28-S and 56-S mixers as an extra.

PAVING MIXERS

(a) Only full caterpillar tread or four wheels shall be used on 12-E and 21-E machines, and four wheels only on 7-E machines.

(b) Maximum width of skip 4 ft. from end shall be 100 in.

(c) Power steering control shall be used in full caterpillar and hand steering on four-wheel machines.

(d) Hand power boom swing only shall be used.

(e) Maximum speed of travel of mixer shall be 1½ miles per hour and minimum ½ mile per hour.

(f) The batch transfer derrick shall have a reach of 14 ft. from center line of machine as standard.

(g) Engine tools only shall be furnished on the 7-S mixer. On the 14-S, the 21-S, the 28-S, and on all paving mixers the manufacturer shall furnish all necessary special tools and a kit of standard tools to be agreed upon by the Manufacturers' Committee.

(h) An auxiliary hoisting drum may be furnished only on the 7-S as special equipment.

MISCELLANEOUS RECOMMENDATIONS

Shafts and Gearing—The sizes of shafts, keys, keyways, gears, and the composition of gears shall be referred to the American Society of Mechanical Engineers for recommendation as to procedure in standardization.

Standardization of Power—The question of standardization of power with reference to requirements for different machines shall be referred to the A.S.M.E. for advice as to proper procedure.

Safety Devices—All working parts shall be guarded in accordance with the requirements of state laws. Paving mixers shall be provided with safety devices to protect men when the skip is being lowered.

Standardization of Names of Parts—The nomenclature of the Concrete Mixer Association, with additions recommended by the Manufacturers' Committee above named, to bring this nomenclature up to date, shall be adopted as standard.

Name Plate—A name plate giving the standard rating of the machine, its capacity for different portions of mix and such other data as may be later determined, shall be affixed to each machine. A committee of three manufacturers shall pass upon the plate and manufacturers shall obtain the right to use this plate from the A.G.C. It is recommended that pending adoption of American Standards, the plate state that the machine meets the standard A.G.C. requirements as approved by the Joint Committee of manufacturers and contractors.

Lubrication, Bearings and Anti-Rust Paint—The manufacturers shall fully, effectively and honestly set forth in their printed matter, information on the principles of lubrication, care and composition of bearings and material and the use of anti-rust paint as used in their machines.

COMPOSITION OF COMMITTEE

The Joint Committee on Construction Equipment is headed by C. E. Bement, chairman, Novo Engine Co., Lansing, Mich., and includes the following members representing manufacturers:

H. B. Bushnell, Western Wheeled Scraper Co., Aurora, Ill.; Phillip Koehring, Koehring Co., Milwaukee; F. H. King, Marion Steam Shovel Co., Marion, Ohio; H. H. Baker, Sterling Wheelbarrow Co., Milwaukee; H. W. Howard, General Motors Truck Co., Pontiac, Mich.; C. D. MacArthur, Blaw-Knox Co., Pittsburgh, Pa.

Representatives of the users of equipment on the committee are:

H. V. Coes, American Society of Mechanical Engineers; Stanley D. Moore, Moore-Young Construction Co., Waterloo, Iowa; W. A. Rogers, Bates & Rogers Construction Co., Chicago; A. P. Greensfelder, Fruin-Colton Contracting Co., St. Louis, Mo.; W. D. Hill, Samuel Gamble Co., Carnegie, Pa.; Frederick L. Cranford, Frederick L. Cranford Co., Brooklyn, N. Y.; W. A. Walbridge, Walbridge-Aldinger Co., Detroit; Frederick Ward, Ward & Tully, Brooklyn, N. Y.; R. C. Marshall, Jr., Associated General Contractors, Washington, D. C.; Ward P. Christie, secretary, 1038 Munsey Building, Washington, D. C.

Reduce Brick Varieties to Two Standard Sizes

Washington Correspondence

One standard size for common brick and one for face brick were adopted formally at a general conference of manufacturers, distributors and representatives of large consumers held at the Division of Simplified Practices of the Department of Commerce, Washington, D. C., June 21.

The size determined upon for common brick and textured face brick was $8 \times 2\frac{1}{4} \times 3\frac{3}{4}$ in.; that determined upon for smooth face brick was $8 \times 2\frac{1}{4} \times 3\frac{3}{4}$ in. Tolerances and variations in size due to shrinkage while being burned, different clays and other factors, will be allowed, the permissible tolerances to be studied by the American Society for Testing Materials in connection with the American Face Brick Association and the Common Brick Manufacturers Association of America. The final report of these organizations will assist in deciding the standard tolerance and variation which will apply to the approximate standards.

By adopting these two standard sizes, the conference eliminated at least 38 rough brick and 35 smooth brick varieties. A survey of 167 plants producing rough brick and of 141 plants producing smooth brick in 1922 showed that from 80 to 90 per cent of the total output conforms to the standard sizes adopted by the conference. The final conference followed a preliminary meeting held May 11, where elimination of excess sizes was discussed.

Motor Vehicle Production

Production of motor vehicles during May, based on figures received by the Bureau of the Census in co-operation with the National Automobile Chamber of Commerce and covering approximately 90 passenger-car and 80 truck manufacturers each month, are shown in the accompanying table. It will be noted that the May figures for trucks are almost double those for the same month last year.

AUTOMOBILE PRODUCTION
(Number of Machines)

	Passenger Cars		Trucks	
	1922	1923	1922	1923
Jan.....	222,706	81,693	19,398	9,416
Feb.....	254,650	109,171	*21,817	13,195
March.....	*319,638	152,959	*34,681	19,761
April.....	*344,474	197,216	*37,527	22,342
May.....	350,180	232,431	42,983	23,788

* Revised.

Use of Mechanical Loaders for Snow Work Increases

An increased use of mechanical loaders of the elevating bucket type for snow removal work in cities is shown by the sales records of the Barber-Greene Co., Aurora, Illinois. To date, cities and street railway companies have purchased exclusively for snow work 22 Barber-Greene loaders. Chicago is the largest user with four machines. Next, with two machines each, are the cities of Philadelphia and Providence, in addition to three street railways, including the Third Ave., New York, the Boston Elevated and the Springfield (Mass.) Street Railway. Owners of one loader include the cities of New York, Pittsburgh, Springfield (Mass.), Albany and Schenectady as well as the street railway companies of Worcester, Mass., Albany and Ottawa, Canada.

Standards Committee Considers C-I. Gas Pipe Specifications

The American Gas Association has submitted for the approval of the American Engineering Standards Committee three specifications for cast-iron pipe and special castings which, it is said, are in general use for underground gas pipes throughout the United States. The Standards Committee has appointed a large and representative special committee to consider the application for the approval of these specifications, and sponsorship for future revisions under the regular procedure involving the organization of a representative sectional committee to consider and develop any changes required. The following are the members of this special committee and the organizations they represent:

S. G. Flagg, Jr., chairman, American Society of Mechanical Engineers; F. A. Barbour, American Water Works Association; E. A. Barrier, Fire Protection Group on A.E.S.C.; W. Forstall, American Gas Association; A. H. Hall, Gas Group on the A.E.S.C., and American Gas Association; W. G. Hammerstrom, chief engineer, Lynchburg Foundry Co., Lynchburg, Va.; H. Kely Associated General Contractors of America; N. F. S. Russell, U. S. Cast Iron Pipe & Foundry Co.; R. Toensfelt, American Society for Municipal Improvements; W. Wood, president, R. D. Wood & Co.; C. D. Young, American Society for Testing Materials; F. A. McInnes, New England Water Works Association; F. F. Schauer, Natural Gas Association of America; A. W. Claussen, Underwriters' Laboratories; and J. C. Meloon, National Automatic Sprinkler Association.

Sales Managers Organize

The National Association of Sales Managers was organized in Atlantic City, N. J., June 7-8, during the convention of the Associated Advertising Clubs of the World. The officers elected were: President, C. F. Abbott, Victrola Clubs, Inc., New York; vice-presidents, G. W. Hopkins, Columbia Graphophone Co., New York; L. C. Rockhill, Goodyear Tire & Rubber Co., Akron, Ohio, and Martin J. Wolf, Bussmann Mfg. Co., St. Louis; treasurer, A. E. Pitcher, E. I. duPont de Nemours & Co., Arlington, N. J.

Business Notes

ASHER FIREPROOFING Co. will open Cleveland offices in the B. F. Keith building, July 1, under the immediate charge of Kirby Smith, who recently resigned as a commander in the U. S. Navy to become a member of the executive staff in the Asher company. During his service with the Civil Engineer Corps of the Navy, Commander Smith was engaged largely in concrete construction work. In addition to being a graduate of the U. S. Naval Academy, Commander Smith holds a diploma from the Rensselaer Polytechnic Institute.

INTERNATIONAL CLAY PRODUCTS Co., Philadelphia, manufacturer of vitrified clay conduits, has changed its name to the Clemont Clay Products Co., following a reorganization of the old company.

ORTON & STEINBRENNER Co., Chicago, manufacturers of locomotive cranes, dipper shovels and grab buckets announces a reorganization of the company and the election of the following officers: P. A. Orton, president and general manager; E. B. Ayers, vice-president; Herbert Mertz, secretary and sales manager; Harry Shaffer, treasurer and purchasing agent; G. L. Niederst, chief engineer; Alex Orton, works manager. No change in the management, control or policy has been made, nor is any contemplated. The reorganization is occasioned only by the resignation of H. G. Steinbrenner as president and the disposal of his interest in the company.

CONNECTICUT BLOWER CORP., Hartford, Conn., has been incorporated under the laws of Delaware, with capital of \$250,000. The officers are: M. E. Keeney, president; C. H. Keeney, treasurer; C. E. Keeney, secretary. The company has taken over the International Blower Co. and the Hartford Sheet Metal Works. The products manufactured and installed include blowers and exhaust fans, blower systems of all kinds, dust-collecting systems, exhaust systems and ventilating systems. The plant of the International Blower Co. will be utilized until fall, at which time a larger plant will be occupied.

Equipment and Materials

Tractor Mounting for Elevating Bucket Loader

A mobile, self-feeding bucket loader mounted on a standard Fordson tractor is the latest product of the N. P. Nelson Iron Works, Brooklyn, N. Y. It is designed for quick moves from one loading point to another, particularly in the case of road contractors who wish to buy only one loader for handling sand, gravel or crushed stone.

Two features of this equipment are emphasized by the manufacturer.

(1) Instead of crawling in under the elevator, where he cannot see what he is doing or digging, and surrounded by chains and sprockets, the operator now stands on a platform at the side of the machine, with all controls in easy reach and with an unobstructed view of the entire digging and loading operation.

(2) By connecting the elevator directly to the engine, instead of to the usual power take-off, the elevator with its toothed digging spiral runs full speed, while the tractor may be inched

backwards into the pile. The spirals level a 6-ft. cut and material once started in motion keeps moving continuously until picked up by the elevator buckets, which are fitted with digging teeth. An overload release gives the operator ample warning of boulders or undiggable material.

The capacity of the machine is 40 yds. per hour of material 2 in. and under that a man can shovel without the use of a pick. A governor is installed to control the fuel consumption to the actual requirements. The power take-off remains available should the owner require its use for operating other machinery, while the entire loader attachment can be readily removed and the tractor used for other purposes. A swivel or turning spout is attached to the loader, permitting discharge sideways into truck. Clearance of 8 ft. 6 in. is given under the discharge chute.

All-Steel Crane Scale Has Capacity of 10,000 Lb.

For use on crane booms in weighing, sorting or grading operations where weights up to 10,000 lb. are handled,

the special heavy-duty scale illustrated herewith has been developed by John Chatillon & Sons, New York. In addition to determining the weight of objects handled, the scale is useful in preventing crane overloads and accidents. It is of all-steel construction and its action depends upon four extra heavy, specially tested springs, oil-tempered after coiling. The dial is 15 in. in diameter, clearly etched and easily read. Scales of this type, the manufacturers report, are being used in many industries where overloads on traveling cranes, cables, and other forms of hoisting apparatus might prove disastrous.

Exhibit Shows Durability of Copper and Brass Pipe

The varied uses and durable qualities of copper and brass pipe and fittings were featured in an exhibit by the Copper and Brass Research Association,

tion, New York, at the annual meeting last month in Atlantic City, N. J., of the National Association of Master Plumbers. An outline of the history of piping was presented in a panel of oil paintings, starting with the wooden trough and ending with brass pipes. A fragment of copper pipe 5,400 years old, from Egypt, was secured from the museum in Berlin and displayed at Atlantic City. About half a hundred different brass plumbing fixtures were connected up into a "family tree" as shown in the accompanying illustration. Emphasis was given in the exhibit to the rust-resisting qualities of brass pipe and the increased flow of water possible through a clean pipe as compared with a rusted pipe.

Publications from the Construction Industry

Caterpillar Tractors—HOLT MANUFACTURING CO., INC., Peoria, Ill., features its caterpillar tractors in a recently published 40-p. illustrated booklet. The information is largely in the form of pictures illustrating the varied uses of the company's tractors, particularly in road construction and logging. Complete specifications are

given for the 10-ton, 5-ton, and 2-ton caterpillar tractors.

Centrifugal Pumps—DE LAVAL STEAM TURBINE CO., Trenton, N. J., has issued a 20-p. illustrated pamphlet on its multi-stage centrifugal pumps. After a brief discussion of the principal parts of the equipment, including casing, impellers, shafts and bearings, the text describes manufacturing methods and materials and the testing of pumps before they leave the factory.

Steel Windows for Schools—TRUSCON STEEL CO., Detroit, in its 28-p. pamphlet "Daylighting Schools," illustrates the uses of a large number of types of its window equipment. Detail drawings and photographs of typical installations are preceded by a treatise on school architecture, with particular reference to windows, by John J. Donovan.

Blueprinting Machinery—C. F. PEASE CO., Chicago, describes and illustrates its new printing machinery and drafting room accessories in a 64-p. illustrated catalog. The apparatus featured includes blueprinting, washing and drying equipment, and high power arc lamps. Several pages are given over to drawing instruments, filing cabinets for tracings and prints, drafting tables and tools.

Business Side of Construction

FACTS AND EVENTS THAT AFFECT COST AND VOLUME

Heavy Freight Traffic Reported by the Railroads

Freight traffic in May was the heaviest for that month in the history of the railroads, according to reports just received from the carriers by the Bureau of Railway Economics, Washington, D. C. It amounted to 39,597,582,000 net ton-miles, an increase of 2.7 per cent over the same month in 1917 when the previous record for that month of the year was made. It also was an increase of 41.7 per cent over May last year, when, however, the miners' strike resulted in a curtailment of coal shipments. Because of this strike last year, freight traffic in May this year in the Eastern district showed an increase of more than 57 per cent over last year, while there was an increase of 24 per cent in the Southern district. The Western district reported an increase of nearly 28 per cent.

Substantial progress is being made by the railroads in carrying out the program adopted by the carriers in April, calling for a speeding up in the movement and the heavier loading of freight cars. The daily average movement per freight car in May was 28.6 miles. Except in May, 1917 when an average of 29 miles was attained, this average has never been excelled in any month before and only once equalled, that one time being in the fall of 1920. The average of 28.6 miles was an increase of 0.6 mile over the average for April.

Every increase of one mile in the average movement of a freight car, it is pointed out, is equivalent to the addition of 100,000 freight cars to the country's transportation facilities.

The program adopted by the railroads calls for a daily average movement per

car of 30 miles and for the loading of all freight cars to maximum capacity in an effort to bring the average loading to 30 tons per car for the entire country.

Further Slump in Lumber Movement

The nation's lumber movement for the week ending July 7, as reflected by reports from 392 of the larger commercial mills of the country shows a marked decline from revised reports for the preceding week from 408 mills. Production fell off about one-third, shipments about the same, and orders declined by a sixth, but as compared with this time last year the movement as a whole is substantially larger. The declines in production and shipments are chiefly due to the summer letup and closing of mills for customary semi-annual repairs.

For all the reporting mills shipments were 92 per cent and orders 85 per cent of production; the corresponding figures for Southern Pine mills alone being 93 and 77, and for the West Coast mills 124 and 126. Grouping by themselves the 347 mills with an established normal production, actual production for the week was 74 per cent of normal, and shipments 72 and orders 66 per cent thereof.

The following figures give the summary of the lumber movement for the week ending July 7, the corresponding week of 1922 and the preceding week of 1923:

	Week Ending July 7 1922	Corre- sponding Week 1923	Preceding Week (Revised)
Mills.....	392	366	408
Production, ft.....	188,046,983	164,510,776	284,487,287
Shipments, ft.....	173,451,837	161,756,252	256,060,910
Orders, ft.....	160,497,639	160,665,513	192,972,469

Municipal Bond Sales in June

As a result of the sale of two very large state bond issues the aggregate of state and municipal bonds placed during June, according to the monthly review of the *Commercial and Financial Chronicle*, New York, was swelled to the figure of \$156,366,800, the largest total reached in any month of June, always notable for bond disposals of exceptional extent.

Fewer municipalities issued obligations last month than in June, 1922.

building construction in St. Louis, Mo. The number of municipalities in the United States issuing permanent bonds and the number of separate issues made during June, 1923, were 390 and 550 respectively. This contrasts with 394 and 571 for May, 1923, and 560 and 762 for June, 1922.

Of the fifty-odd representative bond issues included in the tabulation on this page 3 sold at par, 46 above par, and 3 below par. The yields ranged from 4.11 to 5.97 and the rate of interest from 41 to 6 per cent.

Cement Production Ahead of Last Year's Output

Portland cement production in the United States during June, based on figures issued by the Department of the Interior and prepared under the direction of Ernest F. Burchard, of the U. S. Geological Survey, from reports of producers, amounted to 12,382,000 bbl., as compared with 11,245,000 bbl. for June, 1922. The shipments for June of this year and last year were, respectively, 13,307,000 and 13,470,000

*Ten issues.

The large major bond issues last month were for payment of bonuses to war veterans—\$25,000,000 in Kansas and \$22,000,000 in Iowa. Nevertheless, the aggregate of state and municipal bonds that have come on the market during the first six months of 1923 falls considerably short of that for the first half year of 1922, being \$571,803,563 as against \$655,086,150.

Prominent bond issues during the month for public works or other forms of construction included \$6,720,000 5s. for the Moffat tunnel in Colorado; \$5,000,000 4s. for the Chicago Sanitary District; \$5,000,000 4 1/2s. for road and bridge work in New Jersey; \$2,750,000 for roads and hospital in Hennepin County, Minn.; \$2,500,000 for public

Indianapolis Profits By Asphalt Price War

A "war" between asphalt street paving contractors has caused prices for asphalt paving quoted to the Indianapolis board of public works to drop sharply in the last few weeks until the price of \$2.30 a square yard was reached on one project, the lowest quotation on asphalt street paving since 1916, according to John L. Elliott, city civil engineer.

At the first of the season, the prices for asphalt paving started around \$3.20 a square yard. Later the price hovered about \$3.00, and about three weeks ago a sharp drop to about \$2.60 was noted. This was followed by the \$2.30 offer.

bbl., and stocks were respectively 9,219,000 and 10,718,000 for the same period.

For the first six months of this year the production of portland cement was 62,320,000 bbl. a gain of 15,402,000 bbl. over the same period of 1922.

Large Contracts Let During Week

Among the week's announcements of contracts awarded in *Construction News*, pp. 29 to 41, are the following:

Hotel, Cleveland, O., to Crafts Construction Co., \$3,000,000.

College buildings, Greenville, N. C., to J. E. Beaman Construction Co., Raleigh, \$1,025,000.

Bank and office building, Boston, Mass., to A. C. Whitney, \$1,000,000.

Bids Wanted on Big Jobs

Among the projects on which bids are either asked or will soon be called for in Construction News, pp. 29 to 41, are the following:

Factory, Sweetwater, Tex., for United States Gypsum Co., \$1,000,000.

Cement plant, Macon, Ga., for Clinchfield Portland Cement Co., Kingsport, Tenn., \$1,000,000.

Hospital, Nashville, Tenn., for Vanderbilt University, \$2,000,000.

Cement plant, Jefferson City, Mo., for State Highway Commission, \$2,000,000 to \$2,500,000.

High school, Hartford, Conn., for Board of Contr. and Supply, \$1,500,000.
Jetty, New Orleans, La., for U. S. Engineer, \$1,300,000.

Railways Continue Record Loading of Revenue Freight

Despite the fact that loading of revenue freight for the week which ended on June 30, according to the Car Service Division of the American Railway Association, totaled 1,021,770 cars, the greatest number for any one week in the history, the railroads of the United States had on June 30 a total

of 63,636 surplus freight cars in good repair. This is in contrast with the situation that existed during the week of Oct. 14, 1920, when 1,018,539 freight cars were loaded, the best previous loading record, at which time there was a car shortage of 69,517 cars.

Despite the fact that the loading of revenue freight for the month of June has averaged more than 1,000,000 cars a week, the greatest in history for this time of year, there was an actual increase during the month of June of 31,193 in the number of surplus freight cars. Despite this heavy traffic no car shortage has existed.

Weekly Construction Market

THIS limited price list is published weekly for the purpose of giving current prices on the principal construction materials, and of noting important price changes on the

less important materials. Moreover, only the chief cities are quoted.

Valuable suggestions on costs of work can be had by noting actual bidings as reported in our Construction News section.

The first issue of each month carries complete quotations for all construction materials and for the important cities. The last complete list will be found in the issue of July 5; the next, on Aug. 2.

Explanation of Prices—Prices are to contractors in carload lots unless other quantities are specified. Increases or decreases from previous quotations are indicated by + or — signs. For steel pipe, the prevailing discount from list price is given: 45-5% means a discount of 45 and 5 per cent. Charge is 15c. per 100 lb. for cutting reinforced steel into 2-ft. lengths or over.

New York quotations delivered, except sand, gravel and crushed stone, alongside dock; common lump lime, in 280-lb. bbl. net, and hydrated lime f.o.b. cars; tile "on trucks"; linseed oil and cast-iron pipe f.o.b.

Labor—Concrete laborers' rate, 93¢; building laborers (pick and shovel men) 75c. per hr.

Chicago quotes hydrated lime in 50-lb. bags; common lump lime per 180-lb. net. Lumber delivered on job.

Minneapolis quotes on fir instead of pine.

Brick, sand and hollow tile delivered. Cement on cars. Gravel and crushed stone quoted at pit. We quote on brown lime per 180-lb. net; white is \$1.80 for Kelly Island and \$1.70 for Sheboygan. Common labor not organized.

Denver quotes on fir instead of pine. Cement "on trucks"; gravel and sand at pit; stone on cars; lime, brick, hollow tile and lumber on job. Tile price is at warehouse. Linseed oil delivered, in iron bbl. Common lump lime per 180-lb. net.

Atlanta quotes sand, stone and gravel per ton instead of cu.yd. Common lump lime per 180-lb. net.

Dallas quotes lime per 180-lb. bbl. Steel, cement, cast-iron pipe and crushed stone f.o.b. cars, other materials delivered.

San Francisco quotes on Heath tile, size 5 $\frac{1}{2}$ x 8 x 11 $\frac{1}{2}$. Prices are all f.o.b. warehouses except C. I. pipe, which is mill price

plus freight to railway depot at any terminal. Common lump lime per 180-lb. net. Lumber prices are to dealers in yards at San Francisco, for No. 1 fir common.

Seattle quotes on Douglas fir (delivered) instead of pine. Lump finishing lime per 180-lb. net. Hollow building tile delivered. Hydrated lime in paper sacks. Sand and gravel at bunkers.

Montreal quotes on pine lumber. Sand, stone, gravel and lump lime per ton. Cement, lime and tile are delivered; sand, gravel and stone on siding; brick f.o.b. plant; steel and pipe at warehouse. Hollow tile per ft. Cement price is in Canadian funds (the Canadian dollar stands at 97.32). Bag charge is 80c. per bbl. Discount of 10c. per bbl. for payment within 20 days from date of shipment. Steel pipe per 100 ft. net; 2 $\frac{1}{2}$ -in., \$32.76; 6-in., \$108.

Changes Since Last Week

present market, therefore, appears to be toward stabilization at present levels rather than an actual decline.

Pig-iron prices have gradually fallen off, owing to unsettled market conditions and slowness of buying. A fair-sized volume, however, of new steel plate inquiries, for tank and car construction, marks the beginning of the third quarter.

While pig-iron, coke and scrap are lower, there has been no deviation from the \$2.50 base on plates and shapes. Reinforcing bars are still \$2.40 per

100 lb., f.o.b. mill. A fair volume of new demand for structurals has also developed, with a slight slowing down in production, owing to labor shortage and weather conditions.

Steel shapes dropped 10c. and structural rivets 5c. per 100 lb. in Dallas, while reinforcing bars declined 12 $\frac{1}{2}$ c. in Chicago warehouses during the week. Pine timbers rose 50c. in Dallas and Douglas fir declined \$1 per M. ft. in Denver. Linseed oil dropped 1c. in San Francisco, 2c. in Dallas, 3c. in New York and 6c. per gal in Minneapolis.

While prices of certain basic materials have shown a downward trend during the last two months, increased labor costs have offset any gains realized by the buyer. Lumber has dropped materially; premiums charged for quick steel deliveries have disappeared from the market, and such materials as lead and linseed oil have declined with the decrease in demand. Brick, however, has advanced, owing to scarcity, while cement has remained fairly firm throughout the entire country. The general tendency of the

ENGINEERING NEWS-RECORD

DEVOTED TO CIVIL ENGINEERING
AND CONTRACTING

Volume 91

NEW YORK, JULY 26, 1923

Number 4

Toward Society Co-operation

WHILE President Loweth of the American Society of Civil Engineers was expressing only his own views on a matter of society policy when he discussed co-operation at the Chicago meeting, it may well be assumed that his views are the result of a careful analysis of the trend of membership opinion, which should govern the intentions of the committee of the society now studying this most important question. As a prospectus with obvious limitations his remarks contain a few excellent basic principles. The most important of these is the statement that the chief function in co-operation should be to bring about concerted action of various organizations rather than to attempt to speak for them. If the committee of the American Society of Civil Engineers can propose a scheme acceptable to the other engineering societies by which this end will be achieved, society co-operation in the best sense will soon become a fact. It is absurd to think that the whole great and diversified engineering profession can speak as one voice. The thing which needs to be done is so to co-ordinate the thinking of the various important societies that they can readily get together their opinions, whether similar or diversified, and unless those opinions are too diametrically opposed can achieve some degree of compromise which, expressed through the separate voices of the different societies, will come to the public ear with the additional force of diversification and distribution. Details of organization of such a system are very great, and will doubtless be subject to considerable criticism even after they have been worked out by the committee itself, but the principle laid down by the president might well govern the committee in the study of its problems.

Aiding Water-Waste Prevention

CHICAGO water-waste continues, but no longer without official cognizance or attention. Both mayor and commissioner of public works are using in public speeches words, phrases and arguments framed by engineers, mostly from a brief submitted to them by the Western Society of Engineers. In making up the brief the public affairs committee of that organization had in mind just such use and in consequence the conclusions of the brief were short, illustrative, comparative and calculated to appeal as seriously as possible to the councilmanic constituency. Laying stress on savings was not considered as having anywhere near the pulling value as the startling information that 75 per cent of the city had a decidedly inadequate service in the summer when it is most needed. In the last analysis the citizen wants service—he does not get it in Chicago and never will so long as the pumps must deliver into a sieve-like system. The newspapers have given columns of space to the waste-prevention campaign, nearly every item bearing the earmarks of the society's report. If Chicago

ever does stop wasting water the members of the society's public affairs committee may well feel repaid for their noon-hour conferences, where were discussed the pros and cons of political appeals to a strictly engineering administrative policy.

Crude Figures Misleading

PRESIDENT HARDING'S note of alarm over our mounting state and municipal expenses and debts, sounded in a recent speech at Salt Lake City, was unfortunately based on bare totals and percentages. Had the President made no allowance for any factor entering into the increase except the decreased purchasing power of the dollar, he might have been astounded at the result and been forced to commend instead of blame our cities if not our states for their moderation during the seven trying years since 1914. If in addition he had taken into account population growth since 1914, higher capital costs, and increased operating charges due to run-down plants through deferred repair and renewals, and other factors the whole tenor of this part of his address would have needed marked change. Crude bulk statistics, used without qualification, are always likely to mislead, but seldom are they so gravely misleading as in the discussion of state and city expenses and debts sent reverberating over the country by the President.

California Starts Subgrade Survey

IN THE light of the Pittsburg test-road experience with adobe subgrade construction, it is noteworthy that the California road department has begun a field survey of road foundations. Until now all the systematized records available on foundation materials and structure have come from experimental roads and while they are important there is always present the reflection that in some degree laboratory conditions instead of the comparatively unregulated methods of actual field construction are represented in the results. From all reports, however, the California survey will have particular reference to the character of the foundation soil. It is to be hoped that there will go with this soil sampling the best determination possible in each case of the method of preparing the subgrade and of drainage conditions. A soil survey, useful as it will be, is certain to be only a fraction as useful as it would be if co-ordinated with information on construction methods and drainage. The stable subgrade secured with adobe soil on the Pittsburg test road was the result of the method of construction and not due, it would appear, to any unusual character of the material. A soil analyses alone would have shown presumably nothing of the real reason for the success of the foundation. In any event we need to know all that is possible of subgrade structure and drainage in relation to road durability and the soil survey furnishes an opportunity conveniently to secure such knowledge.

Express-Train Service

A STRIKING feature of the new Chicago rapid transit plan summarized last week on p. 104 is the absence of any general provision for express-train service such as is now operated on most of New York City subways and elevated lines. It is obvious from the fact that the proposed subways and elevated lines are almost entirely double-track structures that an express service is not contemplated. It may be that the committee made a study of the needs of the city in regard to an express service on some or all of the lines and that the idea was abandoned as not justifying the additional expenditure required to three-track or four-track the new line. Or it may be that with the proposed unification of the surface lines with the elevated and sub-surface lines the committee considers that stations can be put at express intervals. If so, the practical workings of such an arrangement will be of great interest to all cities now struggling to provide adequate rapid-transit facilities. Its possibilities for providing immediate relief of the transit situation in New York are enormous. The present four-track subways could, during rush hours, be converted into subways with two lines of express service in the direction of maximum traffic. In this case the people would have to be diverted to the surface lines for the last few blocks of their journey. But if this is not contemplated, if the new plan calls for stations at the usual interval of about one-third of a mile, it does not seem that it will be adequate for a city of the extent of Chicago. Relative distances are not so unlike in New York and Chicago that New York's experience in the use of express trains cannot be taken as a criterion. The benefits which New York derives in an increasing degree as traffic increases amply justify the expense of express service; similar benefits are to be expected in Chicago's rapid transit.

Bridge Design and Good Taste

AN ARTICLE which appeared last week in a magazine of opinion denounces the design for the Hudson River suspension bridge at Bear Mountain as ugly, and proceeds to deplore the defacing of a beautiful landscape by such a bridge. One can hardly take exception to this as a setting forth of the author's likes and dislikes, assuming that they are worthy of being brought to general attention. There is no disputing over tastes. But the author is on less sure ground when, after admitting that he is not competent to say what kind of bridge should be built, he continues, "I think I have enough esthetic sense to say that the design is, on the face of it, hopelessly incompetent." Here we have not a statement of likes or dislikes but an arbitrary dictum. It is extravagant enough to be its own answer.

A word, however, on the question of ugly suspension bridges. Beauty is an elusive matter to discuss, but the case in hand is simplified in respect to the important element of esthetic precedent. Not a great number of suspension bridges has been built in the entire world, so far, and there is no agreement of precedent on proportions, or trussing, or other phases of the design. In this virgin field the one certain fact is that the best suspension bridge is the one that is most efficient as a *suspension bridge*, and which gives expression to its functioning most truly and directly. And truth, we have it on the best authority, is beauty. Whether the

line of the cables shall remain above the truss or not, whether the truss must have parallel chords—or, for that matter, whether the towers are to be stone or steel or vertical or inclined toward stream or bank—may be judged by the criterion of how the efficiency of the structure is made greatest, that is by how truly it performs its desired function. We are not compelled to defer to dogmas of taste established by the building of certain bridges some centuries ago, which, famous through hundreds of years, now set the norm of good taste. The suspension-bridge engineer, happily, need not even in highland scenery vindicate his skill in efficient design by building baronial castles in imitation of venerable ruins of a former efficient adaptation to purpose.

So for many years, as at present, the planning of suspension bridges will be a free art, in which the keen analysis of truly efficient construction will tell what is true beauty of form. The art will not have to go through such struggles against fancied doctrines as involved the builder of truss bridges when he undertook to show that straight lines might serve the world better than the beauty of the arch. Nor will it, we hope, become subordinate to copy book esthetics as did those early builders of plate girders who felt obliged to mask the "ugliness" of their web rivets by appliquéd rosettes.

And finally, the oft-repeated cant about defacing Nature's beauty with ugly works of man is worth a few moments' reflection. This matter is one of sharply dissonant opinions. An extreme note is sounded in the article above quoted, when the author asks that a bridge shall "contribute to the beauty of the Hudson" rather than mar it. Many among those who feel the beauty of a landscape will resent the suggestion that a bridge—however beautiful in itself, however ornamented—can contribute to the beauty of the Hudson. Others again, and we think their number will also prove to be many, will deny that a bridge makes the beauty of such a landscape either greater or less; in their view, the landscape remains as beautiful as before, except where concealed by the bridge. The numerous phases of the question are even more in dispute than the question of the inherent beauty of the bridge. Yet it is brought to the front whenever it is necessary to decide (for example) between stone and steel, or girder and arch. On one occasion it will be claimed that steel construction is always ugly and only stone will do; or again, that a hilly landscape with its curving lines demands curved lines also in a bridge. Thus arguments without base or reference point recur and recur, and while dispute concerns itself with harmony the virtues of contrast rarely receive a thought.

At all times, we believe, it will remain an involved and delicate question, quite too delicate to serve as foundation for such rash and bald conclusions as those expressed in the article quoted. When minimum disturbance of the pre-existing landscape with human construction is most satisfying it will be obviously desirable to make a bridge unobtrusive; when it is best that a structure should not insistently claim the center of the picture, a quiet and consistent outline will commend itself. A few such considerations may be set down; but in its larger aspect the question of harmony with Nature will always remain one of good taste—a quality of fully as much value to the bridge engineer as to the architect.

Some Problems in Rail Consolidation

IN THE proposed consolidation of practically all the railways of the United States to form a limited number of large groups or systems, as provided by the Transportation Act of 1920, the railways face a problem which seems likely to rank only second to the valuation problem in point of difficulties and complications involved. This problem is of interest to the engineer from its probable influence upon railway engineering in particular as well as upon railway affairs in general. His main work will come after the final establishment of the several groups. Then it will be his duty to revise and improve physical conditions and operating facilities on various weaker links in new traffic routes which will need to be developed. Nevertheless there are some engineering and traffic complications involved in consolidation which will bear emphasis.

Under the provision for continuing competition in the transportation act, consolidation must provide systems of interlocking and overlapping arrangement, and not merely separate systems serving different geographical districts. The law is permissive merely, although compulsory powers were included in the original draft, but because it was evident that private initiative alone could never reach the stage of devising or agreeing upon a national grouping of the railways, provision was made for suggestive arrangement of systems by the Interstate Commerce Commission.

A tentative series of nineteen groups has been drawn up by the commission as a basis, their lengths ranging from 3,000 to 22,000 miles, and public hearings have been held for the presentation of the views and objections of railway executives, state commissions, commercial organizations and other varied interests. It is unfortunate that the majority of the arguments have indicated destructive criticism, narrow-gage ideas, lack of foresight, and vision restricted by local or selfish factors. The broad question of consolidation in regard to public welfare and national commerce has been visualized only by a few of the many speakers. Few seem to realize that consolidation is not a paper theory but is a very practical and pressing probability.

According to a report prepared by a committee of the National Industrial Conference Board, the railway executives in general favor the principle of consolidation and regard its application as inevitable. Naturally a railroad strong in financial position, earning power, traffic capacity or physical condition might object to having weaker or less favorable roads annexed to it in a consolidated system. But on the other hand a strong company left alone and surrounded by larger competitors might lose much of the financial and strategic factors of its present individual strength. One special difficulty, perhaps, will be in securing harmony when one present road or system is to be partitioned between two of the new groups to insure effective routes and groups.

The final adoption of a series of groups by the Interstate Commerce Commission does not guarantee financial success or operating efficiency for the several groups. Possibly it is not fully realized what great responsibility will thus rest eventually on the shoulders of the commission. It is true that some of the difficulties may prove less serious than expected and may be smoothed away, but new and unexpected difficulties are likely to arise. It is true also that the law provides for changes subject to the final grouping. Such changes

could be made only slowly and after much deliberation, so that they could hardly be relied upon as a means of avoiding or rectifying serious financial or operating difficulties resulting from errors in grouping.

One feature of consolidation in which the engineer is particularly interested is that of the relative physical condition of lines put together to form a group or operating system. With the aid of a good railway map it is not difficult to select logical groups and logical routes within a group. But the map does not show physical conditions. Take certain proposals for linking up through routes between South Atlantic ports and the Great Lakes. In one of these it was proposed to combine two competing lines which are nearly parallel for part of their length, so as to form a duplicate line of heavy traffic or alternative lines in case of accidental blocking of either one line. The lines are physically connected at certain points and the arrangement appears favorable. But it developed that these connections are not well adapted for through service and that considerable new construction would be required at heavy cost to make such a plan workable.

In another case, an east-and-west trunk line was to be given a northward connection to a lake port. But the trunk line objected that this link had such excessive curvature and grades, combined with light construction, that it could not handle the intended traffic except after costly and extensive improvements. Furthermore, a very similar but not directly parallel lake connection of another trunk line is well adapted for the economic handling of heavy traffic. As a result the latter group would have a distinct advantage in handling lake traffic. This situation at once suggests the question of how the less favorable lines are to be handled and how some kind of balance is to be contrived.

New traffic routes are likely to become logical and available in the consolidated systems, but may be composed in part of lines which at present are of a secondary character. It is probable, therefore, that a considerable amount of improvement work will be required in each group to perfect new routes, and to improve operating conditions. Extensive changes in terminals, yards and other facilities may also be foreseen.

While the main problem is the grouping of the railroads throughout the body of the country, a secondary problem is presented by the semi-isolated sections of the country. Thus in regard to the New England railroads there is a question whether they should be consolidated to form a single group with gateway connections to trunk lines of adjacent systems, or whether they should be divided among such trunk lines in order to form New England extensions of the latter. Under the law the grouping is required to retain competition as far as practicable. But in the first case the competition would be that of trunk lines for the traffic of the New England group, while in the second case it would be between the different lines in New England.

In conclusion it may be said that the movement is going forward steadily and that actual consolidation may be regarded as imminent. If the objectors would see the handwriting on the wall they might realize that their interests lie in co-operation rather than in controversy. To the engineer and the railroad operating officer there may be visions of a much greater, more effective and more economic railway system than that which is now composed of numerous separate individual railways, large and small.

Highway Progress and Problems in the Mid-South

South Carolina	North Carolina
Virginia	West Virginia
Kentucky	Tennessee
Missouri	

Seven Southern States Contemplate Road Expenditures Approaching a Billion Dollars—Automobile License Fees and Gasoline Taxes Will Provide the Money—Editorial Review Based on Studies in the Field

In a few years the banner of quantity production of improved roads will pass to the states lying immediately south of the Mason and Dixon Line and including Missouri. To meet this change there must be a large development of all the agencies of highway building. Engineering organizations must be enlarged, materials production increased, equipment service extended and contractors trained in modern road building. All this necessitates a long look ahead and constructive planning by engineers, contractors, manufacturers and materials producers. It is to help in this planning that the following studies of highway progress and problems in the South were undertaken.

The broad outlook has been assumed in these studies. Technique of design and construction is not discussed; it shows no notable variations from good practice in the older road building states of

the North. Instead, the attempt is made to visualize the broad fundamental problems of finance, administration, popular education and traffic development. To get these wide aspects a month of intensive work in the field and some 3,000 miles of travel have been required. The interviews and conferences have not been with road department officials alone but have included bankers, leading merchants, commercial organizations, highway associations and prominent engineers and contractors. Even the viewpoint of the man in the hotel lobby and the smoking car has not been despised. Naturally all there is to learn has not been grasped and only the high points of what was learned are indicated. They, however, seem to present a chart of highway development which can be examined to advantage by all who look to road building as a continuing business for their employment and profit.

Group Problems Summarized

THE WAVE of large mileages in highway construction is moving southward. In the zone of states embracing the Carolinas, the two Virginias, Tennessee, Kentucky, Missouri and Kansas, only Kansas registers an ebb in the flood. Seven states are planning or proceeding with construction programs surpassing in the amount of money involved all but those of a few states. In the next five years the great records of mileages under construction will be made not by Pennsylvania, Illinois, Wisconsin, Michigan and other northern states but by those mid-southern states which have hitherto counted small in the active production of modern roads. Already in North Carolina and Missouri more miles of highway are under contract than in any of the states previously known as leaders in new construction.

Perhaps the best measure of this sweep of highway development toward the South is the expenditure which is being contemplated. In three states, highway bonds have been authorized in the following amounts: North Carolina \$65,000,000, West Virginia \$50,000,000 and Missouri \$60,000,000. In four states legislation has been inaugurated for highway bond issues in amounts as follows: South Carolina \$60,000,000, Virginia \$50,000,000, Kentucky \$50,000,000 and Tennessee \$75,000,000. The aggregate is the enormous amount of \$410,000,000. For 1923-24 the federal-aid allotment to these seven states is something over \$9,000,000. Assuming a construction period of ten years, continuing federal aid, normal county and township road building and the amount of bonds named, the expenditure for roads will amount to something over \$600,000,000, without considering the growth of ten years in traffic and income.

Admittedly this estimate possesses the uncertainty that four of the bond issues are not yet legally authorized. However, in each state empowering legislation barely failed to pass the legislature last winter because opinion had not crystallized on the preferable method of financing. In no state of the four was public sentiment against comprehensive improvement or averse to heavy expenditures for such improvement. In brief, the most intelligent observers of the trend of thought in highway matters in each state express confidence that at another session of the legislature, if bonds are not authorized, some adequate means of financing an equivalent public roads development will be provided.

There is clearly enough a situation, under the circumstances outlined, which concerns engineers, contractors and manufacturers deeply in a business way and which affects largely the construction-economic direction of public works policies. To present this situation particularly as it interests the engineer, contractor and manufacturer and incidentally in its broader economic aspects, an editorial survey has been made on the ground, from which certain conclusions may be formulated.

Each state of the group has its special problem. In North Carolina, West Virginia and Missouri, the three states whose systems are financed, the problems are progressive construction of improved roads and current maintenance. Virginia has a problem in methods of financing. In South Carolina a lagging disposition adequately to finance road improvement has to be overcome by education. Education again is the problem in Tennessee, but here in road administration policies. Kentucky has a complicated problem in recovering from county control. Virtually all of these problems exist to some extent in each state; together they constitute the group problem of the mid-southern states.

Area and Population—In round figures the group has

an area of 300,000 square miles and a population of 16,000,000. The average population per square mile in no state of the group varies more than five persons from the group average population of 53 per square mile. In the seven mileage-producing states contiguous at the north and including Michigan the area is nearly the same and the population is twice as great.

The two outstanding characteristics of highway development in the mid-southern group of states are:

1. Highway improvement has for its purpose, more than in the North, the development of territory and creation of traffic.

2. For each dollar spent in road improvement there is a greater charge than in the North on each individual and each unit of property value.

In undertaking the expenditures which have been indicated these states are therefore evidencing an appreciation of transportation value and a boldness in investing for its attainment which are not surpassed in the older road building states of the North. This should be set down, it would seem, as the *first fundamental group characteristic* in highway development of the mid-southern states.

Present Status of Highways—These states have no systems of modern roads. They all have improved roads in isolated stretches leading out from centers of population but no considerable mileage of connected and correlated roads. In a measure these statements should be modified in respect to North Carolina and West Virginia, which for two years have been actively building modern roads and are approaching completed systems, but they accurately represent the conditions in these two states at the beginning of construction two years ago. Creation of state road systems virtually from the beginning—for the nucleuses of existing improved roads is scarcely important—is the *second fundamental characteristic* of the group.

Production of a maximum mileage of road usable throughout the year except for a few weeks of the worst weather is the essential road development task. This is well understood by the state highway officials and appears to be sensed in a considerable and increasing measure by business and industrial leaders. It is planned to be secured in two principal ways:

1. Progressive construction, or rapid construction first of permanent grade temporarily surfaced, to be improved later, as traffic develops, by paving.

2. Intensive maintenance, established over the entire system so as to give highway service, prior to construction, in every part of the state.

At present North Carolina is the high exemplar of these practices, but Missouri is following closely and the beginning is apparent in the other states. It is a fair conclusion that the *third fundamental group characteristic* is progressive construction and immediate full-mileage maintenance.

Topographic Conditions—Five states of the group—the two Carolinas, Virginia, Tennessee and Kentucky, are remarkably similar in general topography. In the three seaboard states there is a low coastal plain rising to a higher plateau known as the Piedmont region, and in the west a rugged mountain section. Tennessee and Kentucky have their mountains in the east and from them a rolling plateau sweeps west and gradually descends to the Mississippi River. In these states the highest development is in the plateau region, except for a few important coast and river cities. West

Virginia is uniformly mountainous with no marked regional divisions of topography. Missouri is hilly upland, with a marked mountainous district of the Ozarks and an equally pronounced river bottom area in the southeast.

It follows from these topographic conditions that there is an outstanding group problem of regional planning of highways. This problem shows several phases of which two attract most attention. One is the varying engineering task of mountain construction involving heavy earth and rock excavation; upland construction in industrial and agricultural country where traffic introduces a surfacing problem, and low-land construction complicated by stream crossings and overflow conditions. These are tangible difficulties, which is not true of the difficulties of the other phase of the regional planning problem, namely, sectional jealousy growing out of the provincialism of previous county control of all highway enterprise. It is fair, then, to call the *fourth fundamental group characteristic*, a problem in regional planning.

Financing and Public Sentiment—It is this lingering idea of county rights which has obstructed state financing, although in general the main reasons for delay are: (1) Doubt whether such large expenditures can be afforded and (2) debate whether a bond issue or a pay-as-you-go policy is the sounder method. Public sentiment in practically every state of the group favors improvement on an extensive scale, but it is undetermined as to the wisest method of financing. Everywhere, unfortunately, discussion is tinged with partisanship, which is forgetting the economic and business question in the determination to win personal victory. This situation, however, is largely incidental and may be overlooked in the certainty, which observation indicates, that education is crystallizing public opinion. A public going to school in highway affairs is almost the first impression one gets of the present situation in the border-line states of the South.

Turning to the proposed plans of financing, whether an issue of bonds or a pay-as-you-go method is considered, resort to a general tax is nowhere being advocated. Indeed great effort is being expended to kill any suspicion that general taxes will be increased by intensive road building. The money is to come from automobile license fees and gasoline taxes, and such other taxes as now exist. Six states of the group, all except Missouri, now impose a tax on gasoline: 3c. in South Carolina, North Carolina and Virginia; 2c. in West Virginia and Tennessee, and 1c. in Kentucky, an average rate of 2½c. a gallon, which is well above the average rate for the country. The *fifth fundamental group characteristic* is then, that the automobile is to be made to pay for road improvement.

Road Types—There is no group characteristic in road types except that maximum immediate construction of permanent grade surfaced with selected local soil is contemplated. Paved roads are of all the types common elsewhere except that Kentucky rock asphalt has greater use in these mid-southern states.

Recapitulation—The elements which feature the highway problem in these seven states as a group are: (1) Construction primarily to develop territory and create traffic; (2) Provision of immediate highway service by full-system maintenance and quantity production of permanent grade temporarily surfaced; (3) Regional

planning required by the distinct mountain, upland and bottom land sections of each state; (4) Development of financing plans without general property taxation; and (5) Public education in highway economics and administration.

The Two Carolinas

THE TWO Carolinas are far apart in their progress in road improvement. North Carolina ranks perhaps as the most advanced state of the South. In system development West Virginia will probably challenge this claim and Missouri certainly is running ahead in mileage under contract. South Carolina has not been in a position to do what the other states have accomplished. It has limited funds which have to be widely distributed according to county allotment so that both system development and intensive construction have been impossible.

In population and area the Carolinas are quite different. They are closely similar topographically. Both have the coastal plain, the Piedmont uplands and the mountain region, each having its characteristic development and all together presenting the problem in regional road planning which is a group characteristic of the seven mid-southern states. They are alike too in having extended areas of "top-soil," which is one of the most valuable of the natural road surfacing materials. Altogether the problems of the physical development of roads are similar in the two states.

South Carolina

Mobilizing for Highway Development

South Carolina is a state making ready for the period of intensive road improvement which it knows is approaching. Evidence of this appears in economic studies and formulation of plans by the state highway commission and in the inauguration of definite legislation for a bond issue and for centralizing authority in the state and carrying this legislation over to a succeeding regular session, thus protracting the period of discussion preceding action.

With a very determined public opinion that more definite highway development is required, there is no definite popular thought on ways and means. This is more true of questions of finance and administration than of those of amount, location and type of road. There are, among those who are looked to for formative planning, factions favoring (1) centralized state administration, (2) complete county administration and (3) joint state and county administration. Both a bond issue and the pay-as-you-go plan of financing have their advocates. Taking their cues from their leaders, the run of persons uphold this or that plan as may happen.

Of the bills put before the Legislature last winter, one called for a referendum on a \$60,000,000 bond issue to be financed by increased automobile license fees and a gasoline tax, and one specified a state highway system to be constructed and maintained without regard to county boundaries. Both bills were passed by the senate and after consideration in the house were carried over to the next session. It is a fair presumption that the postponement was wise, since a bond issue would be certain to be defeated by popular vote with the people in their present undetermined state of mind, and that an interim period of thought and discussion will help to formulate and stabilize public opinion.

Meanwhile the engineers of the highway commission are formulating tentative engineering and economic policies. As a starting point three classes of public roads are being considered:

1. Those connecting the farm and market which are or ought to be, it is thought, of sufficient local interest to be paid for wholly out of local funds.

2. Those connecting every market of consequence in the state directly with the next larger markets so as to get a connected system of inter-market roads. These roads, it is considered, are of interest to the entire state, and should be paid for at least in large part by the state.

3. Those roads connecting the principal centers of this state with the principal centers of other states. These are of national significance and ought to be paid for at least in part by the nation.

With 52,000 miles of public roads it is estimated that between 8 and 9 per cent, or from 4,000 to 4,500

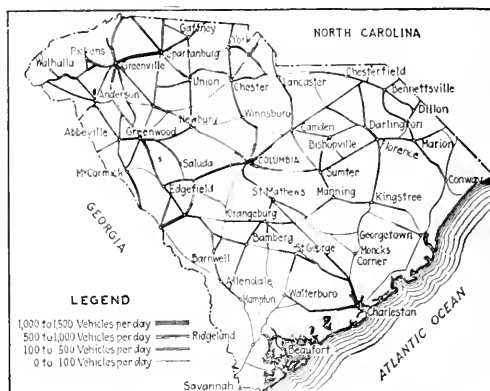

FIG. 1.—APPROXIMATE DISTRIBUTION OF HIGHWAY TRAFFIC IN SOUTH CAROLINA

miles, will eventually have to be included in the state system "if all centers where farm products are marketed in sizeable quantities are to be connected adequately." The present system, as of Jan. 1, 1923, includes 3,519 miles. Type of improvement and its cost have been carefully considered.

Tests made by the department engineers indicate savings up to 50 per cent in gasoline consumption between operating a motor vehicle on fair earth roads and on pavement. Between average unimproved earth roads and the better sand-clay and top-soil roads the saving may run as high as 30 to 40 per cent. Assuming that sand-clay roads cost \$5,000 and paved roads \$30,000 a mile, Charles H. Moorefield, state highway engineer, speculates on the problem as follows:

"If only 1c. per vehicle-mile is saved, 100 vehicles per day would mean a saving of \$360 per mile per year, which would pay 5 per cent interest on \$5,000 and leave over \$100 per year to help with the maintenance. One thousand vehicles per day would mean a saving of \$3,600 per mile per year and would justify any sort of pavement. The actual saving, in cost of operation, of course, would be much more than 1c. per mile as between an average unimproved earth road and a good sand-clay road, particularly if the latter is well maintained. In fact it is estimated, from such information as is had, that the average cost of operating a Ford automobile is approximately 10c. per mile for the unimproved roads in good weather, 6.5c. per

or not. In the matter of the working out of the theory of immediate full-system maintenance without respect to the progress of construction, Frank Page, chairman of the North Carolina Highway Commission, says:

"It has been demonstrated by North Carolina's assuming control of a large mileage of highways for improvement and by the establishment of immediate intensive maintenance that the public at once realizes something is being done. The adoption of the combination patrol and gang system of maintenance, employing motor trucks and tractors for all operations, demonstrated to every section of the state that results were being accomplished every day. The same standard of work and uniformity of practice was maintained throughout the entire state, and, combined with the tremendous extent of the operations, gave immediate and better service to traffic and satisfied an impatient and jealous public which did not expect to see the results realized in so short a time."

A New Method of Testing Hardness

A HARDNESS test differing quite radically from existing tests based upon scratching or penetration of a ball or a sharp point has been worked out by Edward G. Herbert, Ltd., of Manchester, England. An instrument called the Herbert pendulum hardness tester

the hardness figure found in this time test and the Brinell hardness number has been established by tests, as follows: For time-test numbers T below $33\frac{1}{2}$, the Brinell number is $0.3 T^2$, while for time-test numbers over $33\frac{1}{2}$, the Brinell number is $10 T$. The time of ten oscillations on glass is 100, so that the time-test hardness number for glass is 100. This is with a length of pendulum (height from bearing surface of ball to center of gravity) of 0.1 mm.

A test of another kind may be carried out by tilting the instrument to one side until the level bubble is at zero on the scale, and then releasing it. The reading of the level bubble at the end of the first swing is taken as the hardness number. In the case of glass this figure is 97, while annealed carbon steel gives 41, soft cast brass 4, and lead 0.

In the photograph herewith the instrument is shown applied to a cutter whose hardness is to be tested. The cutter is held in a ball-and-socket adjustable vise which is built by the makers for use with the instrument.

Streets of Canterbury in the Days of Henry VIII and Elizabeth

FOR the benefit of Canterbury pilgrims and residents after the days of Chaucer, or in the reigns of Henry VIII and Elizabeth, street lighting, watering, and cleaning at private expense, and scavenging at public expense, were ordered in the following terms, according to excerpts from Bunce's manuscript abridgement of the minutes of the Courts of Burghmote, cited by P. H. Warwick, city surveyor and engineer, in a paper on "Roads of Canterbury, Ancient and Modern," read before a district meeting of the Municipal and County Engineers and published recently in *London Surveyor*:

Street Lighting—Twentieth of November, 55th Henry 8th. From henceforth during Winter every dark night the Aldermen and Common Council and every Inn holder shall severally find one candle will light at their doors on pain of forfeiting 6d., and the other inhabitants are to do in like fashion upon reasonable request under the same pain, and if any lanthorn shall be stolen the offender shall be set on the Pillory by the discretion of the Mayor. The candles are to be lighted at 6 o'clock, continue till burnt out.

Street Cleaning—Sixth November, 35th Henry 8th. The inhabitants of the city are from henceforth to keep clean their pavements belonging to their houses on every Friday or Saturday, and are to carry away the Dung from the pavements to a common place theretofore ordained called the Black Dyke, and no persons are to lay any Dung under their walls on pain of 2d., one half to the Chamber and the other half to the Officer assigned on. The penalty is to be levied by distress.

Street Watering—Fourteenth July, 32nd of Elizabeth. In course of the hot weather every inhabitant of the city is to water the street adjoining his house on pain of 3d., to be levied by distress.

First Scavengers—Eleventh March, 42nd of Elizabeth. The Mayor and Aldermen are to provide a Scavenger or Scavengers for cleaning of the streets, who shall be paid their wages by a taxation on the inhabitants.

Water Costs More Than Doubled at Reading

The cost of supply water at Reading, Pa., increased from \$15.62 per million gallons in 1913-14 (April to April) to \$32.82 in 1921, according to the latest published report of Emil Nuebling, chief engineer of waterworks. The figures given include all maintenance, but no capital charges. Pumping costs increased from \$5.97 to \$15.50 per million gallons. The revenue per million gallons was \$48.41 in 1913-14 and \$45.13 in 1921.

HARDNESS TESTER APPLIED TO A CUTTER

is being built and sold by them for the purpose of the new tests. As indicated in the view herewith, the instrument consists of a bow-shaped weight, adapted to swing as a pendulum on a point support provided at the center of the bow. At this support the bearing is a 1-mm. ball of either ruby or hardened steel. On top of the bow is mounted a spirit level.

With this instrument two kinds of test are possible. What appears to be the preferred test of the makers is called the time test. In this, the instrument, placed with its bearing point on the surface to be tested, is given a very gentle impulse so as to oscillate on its support; the time, in seconds, of ten complete oscillations is taken as the hardness number. From a statement by the makers, an empirical relationship between

Flood Relief Plans for Red River of the North

Interstate Relations Complicate \$6,000,000 Plans for Detention Lake and Improving 400 Miles of Winding Channel

PREVENTION of overflow from a sinuous river channel and drainage of flood waters from the adjacent lands are the main points of a project for the protection of the valley of the Red River of the North, where increasing settlement makes the periodical flooding increasingly serious. Some form of interstate organization will be necessary for carrying out and supervising the project effectively, since Lake Traverse, at the head of the river, forms part of the boundary between Minnesota and South Dakota, while the river forms the boundary between Minnesota and North Dakota. Channel improvement being one of the main features in the project, maintenance of the channel in its improved condition will be essential to success and will be one of the problems for solution by whatever supervisory body is organized.

This flood control and drainage problem has been the subject of an extended investigation by the U. S. Department of Agriculture, under the direction of S. H. McCrory, chief of the division of agricultural engineering. The accompanying review of the situation is prepared from a report by P. T. Simons, senior drainage engineer, and Forest V. King, drainage engineer, who have been in charge of the investigation. A preliminary report, dealing with the special features involved at Lake Traverse and the upper end of the valley, was summarized in *Engineering News-Record* of July 29, 1920, p. 225.

The Red River of the North heads practically in Lake Traverse on the western line of Minnesota and flows north to the Canadian boundary, continuing to the city of Winnipeg and discharging into Lake Winnipeg. The problem of the Canadian portion of the river was discussed in *Engineering News-Record*, April 20, 1922, p. 657. The river is fed by numerous tributaries and its drainage area and the main streams are shown in Fig. 1. The south end of Lake Traverse is closed by a low and narrow divide, separating it from Big Stone Lake, which is at the head of the Minnesota River flowing southeast to the Mississippi (see *Engineering News-Record*, July 28, 1921, p. 140).

Although the course of the Red River is due north its channel is so extremely winding that its length from the Lake Traverse outlet to the Canadian line is 456 miles, or about double the straight line distance. This typical condition is shown in Fig. 2. For the first sixty miles the stream is known as the Bois de Sioux River, the Red River proper beginning with the junction of the Bois de Sioux and Otter Tail rivers near Wahpeton, N. D.

Red River Valley—A plain 15 to 30 miles wide flanked by steeply rising ground forms the drainage area of the river, with 35,895 square miles south of the Canadian line. Owing to natural drainage there is comparatively little swamp land in the plain, except along the Bois de Sioux River. Not more than 10 per cent of the drainage area is forested and about 80 per cent of the prairie and cleared land is under cultivation, the remainder being mainly grazing land and town sites. The soil is largely clay and loam.

In this broad and nearly level valley the flood water has very little current and the depth is not great even with a

heavy overflow. But it causes damage to property, interferes with transportation and agricultural work and may result in greatly reduced crop yields. The river has an irregular flow and protracted periods of low water. Its fall is slight, the elevations of the ground surface on the banks being 980 ft. above sea level at Lake Traverse, 963 ft. at Wahpeton, 900 ft. at Fargo, 830 ft. at Grand Forks and 789 ft. at the Canadian line. The channel capacity is about 2,000 and 4,000 sec.-ft. just above and below Breckenridge, 6,000 ft. below the Dakota Wild Rice River, 12,000 ft. below the Sheyenne River, 15,000 below the Buffalo River and 25,000 sec.-ft. below the Red Lake River.

Rainfall and Runoff—Annual precipitation during the 38-year period including 1919 for the 25,755 square miles above Grand Forks has ranged from 12.21 in. in 1910 to 27.76 in. in 1916. On some subdivisions of this area higher figures have been reached, with a maximum of 35.2 in. on 4,225 square miles. The annual and monthly records of rainfall indicate that the maximum annual precipitation will not exceed 30 in. for the entire drainage area south of

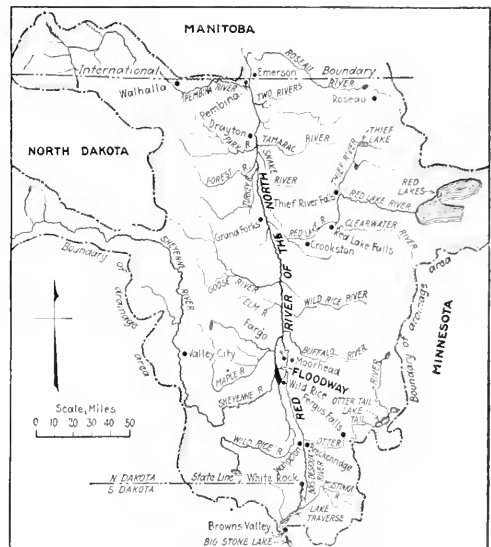

FIG. 1—DRAINAGE AREA OF RED RIVER OF THE NORTH

the Canadian line, 37 in. for areas of 2,000 square miles or more in the eastern section, 25 in. in the extreme western section and 36 in. above Fargo. These maximum conditions are not likely to occur more often than once in 50 to 75 years, and maximum precipitation on the smaller drainage areas is not likely to occur on all these subdivisions in one year.

Runoff records for this 38-year period show an annual runoff from the drainage area south of Grand Forks ranging from 23,590,000,000 cu.ft. in 1911 to 190,880,000,000 cu.ft. in 1897, with a mean of 90,870,000,000 cu.ft. and a mean rate of flow of 2,881 sec.-ft. The shape of the drainage area tends to produce quick runoff. Since the width is nearly equal to the length, the runoff from large portions tends to concentrate at certain points. Maximum monthly records of rainfall and runoff are shown in Table I. Drainage ditches do not materially increase the spring runoff from melted snow, because a majority of these ditches are obstructed by snow and ice so that they do not begin to function until some days after the melting of the snow on the drainage area.

Tributaries and Drainage Ditches—In the upper reaches of the tributaries the fall is much greater than in the Red River, but in the lower parts the fall is slight. Many of

these streams parallel the main river for a considerable distance before finding an outlet. The channels are sinuous and badly obstructed by vegetation. During heavy runoff the general condition is that of increasing bodies of water coming down obstructed channels of small and diminishing slope. These bodies finally unite in a common channel having the same characteristics, resulting in the overflow of large areas of flat land along the river.

Drainage ditches in the flat lowlands have but little fall and their efficiency depends largely upon the conditions of river flow. This drainage work is more extensive on the Minnesota side, where 41.3 per cent of an area of 4,391 square miles is within half a mile of ditches, while on the Dakota side the proportion is only 11.5 per cent for an almost equal area. The upland drainage systems have greater fall and free-flowing outlets. A condition which appears to be beyond relief is that many of the ditches

FIG. 2—PROPOSED FLOOD DIVERSION CHANNEL

are filled with snow and ice in the spring. Tile drainage is very limited as yet but it will accelerate the removal of water in the soil and thus reduce the bad effects of excessive moisture.

Snow and Ice Conditions—Snow accumulates on the drainage area in varying quantities from November to March, inclusive, and has an important effect on the runoff during March and April. For the highest flood on record (April, 1897) the average depth of snow just before the

TABLE II—STORMS IN RED RIVER VALLEY

Duration, Days	Precipitation, Inches		Date
	Total	Max. in 24 Hours	
3	11 10	10 75	July, 1909
8	10 50	3 15	Aug., 1900
4	9 02	4 92	July, 1919
4	8 18	4 31	Aug., 1899
6	7 42	5 86	July, 1897
6	6 93	5 85	Aug., 1908
4	6 13	5 30	June, 1919
3	5 04	3 95	June, 1915

spring break-up was 26 in. and all of this melted in about twenty days. All the larger floods have been due to the melting of snow on the drainage area rather than to precipitation at the time of the flood, although in some cases the flood has been increased by precipitation. Nearly every year more than 25 per cent of the annual runoff occurs in April. This is owing to the melting of snow, as the April precipitation is usually less than 10 per cent of the annual precipitation.

With a northward flow through a region of low winter temperature and heavy ice, spring thaws begin in the upper portions of the watershed and move gradually downstream, causing the runoff from large areas to reach lower portions of the river when the ice is breaking up. This ice lodges against trees and other obstructions so as to retard the current and reduce materially the discharge capacity of the stream. Prof. Chandler's paper on "The Floods of the Red River Valley" (*Journal of the University of North Dakota*, 1918) states that in some cases this ice retardation has raised the water 2 to 7 ft. higher than would have been necessary for the same discharge capacity with a free channel.

Storm Records—For the 26-year period 1894-1919 there were 130 storms with a precipitation of 2 in. or more in 24 hours. Of these, 62 were in June-July, 30 in April-May, 31 in August-September, 2 in March and 5 in October. In duration, there were 41 storms of three days each, 38 of four days, 18 of five days, 17 of six days, 8 of seven days, 7 of two days and 1 of eight days. Eight of these are noted in Table II. The storm of July, 1897, covered the entire drainage area and was the maximum storm of such wide extent.

Storm precipitation during the summer often has a marked effect on the runoff, this effect being relatively greater on the drainage areas of tributary streams because the most intense precipitation occurs in comparatively small areas. Storms sometimes cause maximum runoff on drainage areas up to 10,000 square miles, but on the larger areas, such as that above Grand Forks, the spring runoff due to melting snow is the greater.

Flood Conditions—Serious spring floods due to rain and melting snow occur at intervals of one to fifteen years along the Red River north of Wahpeton. From May to October local floods are caused by storms of very heavy rainfall over areas up to 5,000 square miles. Seven times during the 40-year period including 1920 the Red River at Grand Forks rose above flood stage (El. 819.5 or 40 ft. on the gage of the U. S. Geological Survey). In each case this occurred soon after the spring thaw. High stages occurred in the two consecutive years 1882 and 1883, but the longest period between flood stages was twelve years, 1904 to 1916. Only two of these seven floods were serious throughout the entire valley. Some have been most serious below Grand Forks, but that of 1916 was most serious around Fargo and in the upper parts of the valley.

Conclusions based on the records are as follows: (1) A serious flood may occur in any year; (2) the probable frequency is one in fifteen years; (3) the largest probable interval between floods is thirty years.

Recommended Improvements—From the study of the situation it is evident that adequate drainage of the wet and overflowed lands in the valley will require control or reduction of the floods and the provision of ample drainage ditches to remove excess water rapidly from these lands which have insufficient natural drain-

TABLE I—MAXIMUM MONTHLY PRECIPITATION AND RUNOFF OF THE RED RIVER

Month	Precipitation Inches		Runoff: Billions of Cubic Feet	
	Max.	Year	Max.	Year

Dec.	1.52	1909	6.49	1909

age. The work divides naturally into three parts, which can be carried out separately or as one large project: (1) Lake Traverse and the Bois de Sioux River; (2) the Red River; (3) the Red Lake River.

For the first section, it is proposed to develop Lake Traverse as a detention reservoir by means of a dam at the outlet and a levee at the south end; also to excavate a new direct channel for the Bois de Sioux and to provide a system of drainage ditches (see *Engineering News-Record*, July 29, 1920, p. 225).

Channel improvement and one stretch of stream diversion are the main features of work proposed along the Red River. It is only during times of excessive runoff that flood stages occur and a relatively small reduction of the high stages would prevent overflow. In the opinion of the authors of this report there is no opportunity for detention reservoirs, while levees from 5 to 20 ft. in height along the river and its numerous tributaries would be of prohibitive cost. To relieve the flood flow at Fargo, it is proposed to construct a wide and shallow floodway with a capacity of 2,250 sec.-ft. from the Wild Rice River near Wild Rice, N. D., to the Sheyenne River, a distance of about seven miles. The approximate route of this floodway is shown in Fig. 2, but no definite location has been made. In this way, high stages of flood water would be bypassed around Fargo and discharged below that city by the Sheyenne River. There would be a concrete inlet sluiceway, with gates, but the channel would be formed with gentle slopes so as to be used normally for pasture.

In improving the main channel, its enlargement and the construction of cutoffs are both impracticable, owing to the enormous amount of excavation which would be required and the difficulty of disposing of the material. The most economical and effective plan is considered to be that of clearing the channel of the numerous obstructions which retard the flow and are largely responsible for overflow. Throughout its length the channel is more or less obstructed by trees, brush, bridge piers and other structures, refuse dumps and debris. This condition is shown clearly by the typical cross-sections in Fig. 3, these sections including the normal open channel and the restricted channel at bridges. Particular attention is called to the narrow section at Fargo, which indicates the desirability of bypassing the floodwaters around the city by means of the relief channel noted above.

For the 394 miles from Wahpeton to the Canadian line it is suggested that the entire high-water channel should be cleared of all obstructions except bridges. To maintain this condition it will be well to utilize that part outside of the flow line for pasture or hay. Many of the bridges are old and new ones should span the entire channel and be placed above high-water level. The high-water channel would include from 100 to 200 ft. on each side of the present low-water channel, giving a total cleared width of 300 to 600 ft.

Red Lake River—An important factor in the Red River flow below Grand Forks is the flow from Red Lake and the Red Lake River. Except for high rolling land at the south, the lake of 441 square miles is in low flat country. The high-water level of the lake is 1,177 ft. or 4 ft. above low water. A project developed by the U. S. Engineers provides for limiting the range to 3 ft. by a control dam giving a maximum elevation of 1,174 ft. This dam would have concrete floor and piers with stop-log sluices between the piers. The present ill-

defined channel below the lake would be improved for a distance of 45 miles. By thus lowering the lake level, local flooding would be prevented and drainage facilitated, while the increased flow would benefit present and future water-power plants on the Red Lake River.

Cost of Improvements—The estimated cost of the entire project is \$6,179,000 at 1920 prices. This amount is distributed as follows: Dam and sluices at Lake Traverse, and new river channel and drainage ditches along the Bois de Sioux, \$1,400,000; channel clearing along the Red River, \$3,395,000, with \$250,000 additional for extending the work 30 miles beyond the Canadian line to make the improvement fully effective; Wild Rice River floodway, \$355,000; Red Lake and Red Lake River improvement, \$779,000.

Possibility of flooding now makes the farming of large areas of the valley impossible or hazardous, and overflows which do occur interfere with urban activities and transportation. In the great flood of 1897 the loss was estimated at \$7,000,000 and a similar flood at the

FIG. 3—TYPICAL CROSS-SECTIONS OF RIVER
Note restricted and obstructed channel at bridges.

present time would cause much greater loss. It is considered that these unfavorable conditions can be eliminated by the proposed improvements, which would lower the flood level by 5 ft. or more. Further, the benefits to be derived would warrant considerably greater expenditure than will be necessary for relief.

Organization—For this interstate project it would be necessary under existing State laws for organizations in the three states to enter into an agreement as to the distribution of cost. To insure satisfactory results it is essential to have a definite centralized control during construction and for subsequent maintenance. One plan suggested in the report is for each state to organize a drainage district including the lands benefited. The officers of these districts could then meet as one board having charge of the project as a whole. As an alternative, it might be possible to enact legislation providing for a joint commission. In any case, legislative action should provide authority for maintenance of watercourse channels, since lack of such authority has resulted in damage due to channel obstruction and ungoverned flow.

North Dakota Reservoir Project—A system of reservoirs and other works for control of floods of the Red River is proposed by Herbert A. Hard, chief engineer of the North Dakota Reclamation Commission. In a recent report he states that the losses during the three flood years 1915-1917 amounted to \$50,000,000 and that the total cost of reservoirs, canals and controlling works will be about half that sum. This work by the State is being planned to meet the terms of the U. S. War Department. Impounding reservoirs are proposed at Lakes Traverse, Tewaukon, Ottortail and Red, at three points on the Sheyenne River and on the Pembina River west of Wahalla. The following is from a statement submitted by Mr. Hard.

An intensive survey has been made of the Sheyenne River gorge, especially for a hundred miles from Valley City to the headwaters. This narrow gorge varies from 100 to 250 ft. in depth and from 1 to 2 miles in width at prairie rim. The flood plain varies from a few rods to a mile in width. The gradient varies from 1 to 3½ ft. per mile. A stadia survey covered the entire gorge. Topographic maps are complete, as are preliminary designs for the proposed control dams, which are to be of the earth fill type with puddled clay core and concrete controlling works and spillway.

Taking as an example the dam ten miles north of Valley City, designs were made for heights of 50 and 60 ft. The valley floor is at El. 1239. A dam with spillway crest at El. 1280 will contain over 630,000 cu.yd. of earth and, with its concrete culvert, spillway, etc., will have an estimated cost of \$344,134, exclusive of land and damages. This will give reservoir capacity of about six billion cubic feet and will afford relief from floods for the lower Sheyenne and Red valleys. For the Wild Rice River, a small dam at the outlet of Lake Tewaukon would partly control the flood stages and reduce the crest at Fargo. Alternative designs for dams 6 and 8 ft. in height have been prepared, with costs of \$8,000 and \$20,000 respectively. At this reservoir, as well as at Lake Traverse and Red Lake, there would be very little damage by flooding of surrounding lands.

The state and federal reports recommend a dam near the outlet of Lake Traverse, which lake is 30 miles long and from 1 to 3 miles wide. It can be made to impound 12,000,000,000 cu.ft. of water and will remove the flood menace of the waters of the Mustinka River, Minn., which caused much of the loss in 1915-1917. That loss became the basis of the \$1,500,000 damage suit brought by the Dakotas against the state of Minnesota. The federal estimates, made during the war, are \$1,400,000 for the Traverse project or \$12.50 per acre of the lands protected. Estimates on improvement of the Red River channel from the outlet at White Rock to a point thirty miles north of the Canadian line are \$4,000,000 or \$8 per acre. The state has made no survey of the channel, but from the work on Lake Traverse prior to and during the federal survey, its post-war estimates are about two-thirds of the above values.

The War Department has made similar surveys of Red Lake and Red Lake River, Minnesota, and the state and federal engineers are in agreement on the efficiency of impounding reservoirs and channel improvements as means to avert floods in the afflicted valleys which have each caused losses equal in amount to the cost of all the improvement projects recommended.

Concrete Poles for Large Swedish Transmission Lines

Concrete Poles Produced by a Centrifugal Process Prove to Be Economical and Have Unusual Tensile Strength

By F. A. BRACKMANN
Berlin-Lankwitz, Germany

ON ACCOUNT of the high price and the cost of maintaining iron structures, and the comparative short life of wooden structures, Swedish electric light and power companies have turned their attention to the development and use of concrete poles for transmission lines. The line from Trollhättan Falls in south central Sweden to Vaestres, northwest of Stockholm, is the largest one on which they have been used. It is about 200 miles long and at present transmits current at 110,000 volts. It is intended to increase the voltage to 240,000 later on.

Eight hundred concrete poles produced by the centrifugal process were used in the construction of this line. They were erected in pairs. The first few hundred were

FIG. 1—TESTING ONE OF THE CONCRETE POLES

A pole 64 ft. long bent 7½ ft. out of line at the top without showing signs of failure.

connected by an iron transverse beam, but in view of the favorable result of tests made in the course of construction reinforced hollow beams were used later on.

These carry two cables between the poles and two at the ends outside. The length of the cross beam is about 54 ft., and the width between the two poles is 36 ft. According to the changing local conditions along the line, and the variations in the load from 1,200 to 1,400 lb., four different size poles were made, 56 to 59 ft. in

FIG. 2—A DOUBLE REINFORCED-CONCRETE POLE
A pole 61 ft. high on one of the smaller lines subjected to a top load of 10,000 lb.

length, and in diameter from 9 to 10 in. at the top, and from 18.5 to 23 in. at the bottom. The average thickness is about two inches. Nearly six per cent of them were tested, and some of them, about one per cent of the whole number, were subjected to bending stresses till fracture occurred. It was stipulated that the latter had to stand at least four times the highest ultimate load at the top. The others had to be subjected to double that load without showing any cracks or alterations of form.

The tests proved however that the poles were exceedingly elastic, and could carry six to eight times the highest ultimate top load. During the tests the load was taken off several times, and the top went almost completely back into its original position, showing that the bending was of an entirely elastic nature. In some cases when the breaking stress had been reached, cracks from the tensile stress outside the bend, and signs of excessive pressure inside the bend appeared at the same time, which shows that the tensile stress which centrifugal concrete will stand is considerably above the usual for concrete. Fig. 1 shows one of the poles, 64 ft. long, being subjected to a bending stress of 7,300 lb., bent 7½ ft. at the top without any signs of damage. The poles were tested at an age of six to seven weeks.

Of the poles and the beams which were manufactured at the works of a German firm at Cossebaude near Dresden, two-thirds were transported by rail the whole way, via the ferry Sassnitz-Trelleborg, and the rest were shipped by lighters from Stettin. Considering the great stresses to which the transport subjected them,

it speaks well for their quality that all arrived in first-class condition.

The poles are manufactured in a wooden mold, which is revolved in a special machine. The mold consists of two half-round forms, and is lined with sheet iron. The reinforcement is formed by rolled rods, of open-hearth material, placed longitudinally, which are interwoven with three spirals of wire one within the other. It is wound upon a special automatic machine, so that uniformity in the measurements of the spiral and in the strength of the poles is insured. The spirals influence the fracture stress comparatively little, but they determine to a certain extent the rigidity of the pole, and by using three spirals it has been possible to reduce the bending to ½ per cent of the length at the normal load, and to 1½ per cent at the double load. In order to give the maximum strength to the pole, care is taken that the reinforcement comes as close as possible to the circumference, and is at an equal distance away from it. Small slabs of concrete are therefore fitted to the outside of the reinforcement to keep it in the proper position within the mold. The cement mortar is mixed in proportion of one to three, and some asbestos fiber is added for additional toughness.

After the wire structure and the cement have been put into the mold, this is closed, and put into a machine which revolves it at a speed of 500 to 1,000 revolutions per minute, according to the diameter of the pole. The excessive water in the mortar accumulates in the hole in the center and in striking the wall of the pole during the revolving increases its compactness. The fear that the cement would be thrown to the outside, and that the mixture would become less rich towards the center has been proved unfounded.

After revolving the mold in the machine for about ten to fifteen minutes it is taken out, the lid at the end is removed, and the water is poured out of the center. The pole is left in the mold for one to two days. It has then set sufficiently to be taken out, and is kept in moist sand for about three to four weeks.

Concrete Motorcycle Track in Prague

A combined horse-racing and motorcycle-racing track was built recently in Prague, the cycle track being a concrete frame-and-slab structure surrounding the running track. This cycle track is of unusual design, as the cross-section herewith indicates. It has a measured length of 1,125 m., and is 8 m. wide on the straight and 9½ m. at the middle of the curves. The banking follows the curve of a cubic parabola, and is said to have been laid out for a maximum speed of 180 km. per hour.

CONCRETE BENT OF PRAGUE CYCLE-RACING TRACK

At the upper side the track structure continues vertically to form a protection rail, formed by four 3x6 timbers. The track is briefly described by Dr. J. Polivka, of Prague, in *Beton und Eisen* of May 20.

Underground Contamination of the Bad Axe Water Supply

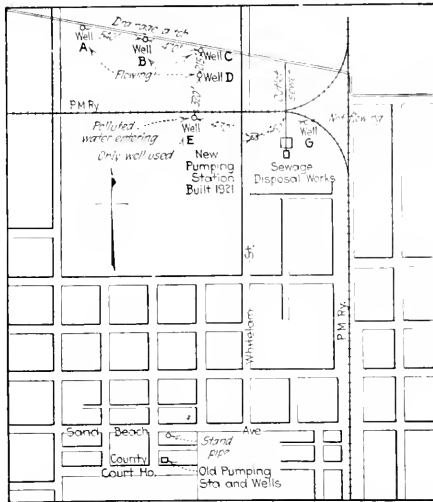

Pollution Entering Unused Well 430 Ft. from Used Well Reached Latter Through Fissure Opened by Dynamite

By W. C. HERN

Assistant Engineer, Bureau of Engineering, Michigan Department of Health, Lansing, Mich.

FORMATION of fissures by dynamiting wells probably is accountable for the pollution of the water supply of Bad Axe, Mich. The dynamiting took place several years ago but only recently have the dangerous conditions become possible.

Bad Axe is a city of 2,200 population, located in the upper part of the thumb section of Michigan in a level

RELATIVE LOCATION OF USED AND UNUSED WELLS AT BAD AXE

sandy lake bed area. In the vicinity of this city Marshall sandstone is the upper layer of the bedrock formation and is covered by only 30 to 50 ft. of glacial drift. The sandstone is several hundred feet thick. The upper layer is relatively free from water-soluble materials and furnishes water of a hardness of about 200 p.p.m. Previous to 1921 the city procured its water supply from three 6-in. wells, each about 150 ft. deep, located in the south central section of the city. These wells when first driven flowed a limited quantity of water. To procure a sufficient quantity for the city during recent years they have been pumped by air-lift.

Several years ago one 8-in. and six 6-in. wells were drilled in the northern section of the city to be used for supplying water to a proposed beet-sugar mill. These wells were drilled to a depth of 260 ft. and after drilling was completed a heavy charge of dynamite was exploded in the bottom of each well. The amount of dynamite used is not known, but an observer stated that water spouted up more than 50 ft. high from the explosion. The proposed sugar mill was not built and these wells were not used for several years. Persons living in the vicinity state that a considerable quantity of water flowed from them continuously.

Because of the excessive cost of operating the air-lift pump at the old pumping station the city authorities decided in 1921 to build and equip a new station to pump water from one of the seven unused wells. This installation was finished during the fall of 1921. Tests had shown that the largest of these wells would furnish sufficient water for the city when the head was lowered not more than 10 to 15 ft. Water from this well has a hardness of 315 p.p.m. but as the city has no important industries which might be affected by hard water the additional hardness was not seriously considered.

A state law requires that plans of public water systems be submitted to the State Department of Health. An engineer was not employed for this work and no plans were prepared or submitted, nor were samples of water sent by the city authorities to a laboratory for either bacteriological or chemical examination. On Nov. 30, 1921, a sample for bacterial analysis was collected from the city supply by a representative of the State Department of Health who was collecting routine railway supply samples in U. S. Public Health Service work. This sample complied with the requirements of the Public Health Service standards.

About March 25, 1921, several cases of intestinal disorders were treated by physicians of the city who judged that the sickness was a form of influenza. This trouble was not brought to the attention of the State Department of Health. Near April 1 a second epidemic of intestinal disorders developed which by April 8 affected at least 75 per cent of the population of the city. On April 12 the State Department of Health was notified of the trouble by the city authorities and was asked to send investigators to the city. A physician and a sanitary engineer were at once detailed to this work. On arriving in the city it was learned that the authorities had circulated handbills advising that all drinking water be boiled.

An examination of the new source of water supply was started immediately. Records showed that the casing of the 8-in. well in use extended down 40 ft. to rock. A screw cap was fitted to the top of this casing and a 4-in. suction pipe from the pump was screwed into the cap and extended about 40 ft. down into the well. All of the fittings appeared to be in excellent condition. To learn if the casing might be leaking a motor-driven air pump was borrowed from a garage and connected to a tap in the cap of the casing. An air pressure of 16 lb. was maintained after the air pump was stopped, which indicated that the casing and connections outside the suction pipe were free from leaks.

It was learned that the old source of supply had been used on different occasions for fire protection. The times when this was used seemed to correspond with the times of the outbreaks of sickness closely enough to direct suspicion in this direction and it was found that a small reservoir at this station was not properly protected against contamination. However, bacterial examination showed the water from the new pumping station to be grossly polluted but that from the old station to be free from contamination.

A further investigation was at once begun to determine the source of the pollution. Meteorological records from the U. S. Weather Bureau Station at Port Huron showed a rainfall of 0.76 in. on March 24 and 0.42 on March 27. These rains flooded a considerable portion of the area about the new pumping station. It was

found that wells marked A, B, C and D on the map were flowing. Well G was not flowing but water stood in the casing above ground level. After some inquiry well E was located in a large pond of water with the top of the casing submerged. On examination it was found that this well was not flowing but that surface water was flowing into it and was no doubt responsible for the gross pollution in the city well 430 ft. distant as shown on the map.

It would seem reasonable to assume that the fine dense nature of the Marshall sandstone would preclude any danger of contamination traveling a distance of 430 ft. but it is possible that the charge of dynamite exploded in these wells opened fissures through this formation. It has also been learned that in some places a very porous material lies between the upper and lower layers of Marshall sandstone and this porous connection may have been partially responsible for the trouble.

Unusually Large Tank for Testing Working Models of Ships

BY PROF. OTTO COLBERG
Hamburg, Germany

ONE of the most important pieces of reinforced-concrete tank construction carried out in Germany in recent years was the ship-testing tank built at the Hamburg Ship-Testing Institute during the war. The tank has a total length of 1,138 ft. and is built in two sections that can be used either independently or as one continuous tank. When used as one tank it is the longest tank of its kind in existence. The compartments are of different sections. The larger tank is approximately 53 ft. wide, 458 ft. long and 24 ft. deep, while the smaller tank is 491 ft. long, 26 ft. wide and 16 ft. 5 in. deep. The two tanks are connected by a conical tank 65 ft. long. Both tanks are used in testing models of different types of ships, the larger one being used for large models and the smaller tank or the combined tank being used to test small models.

The requirement for the test of models made it essential that the tank be waterproof and of as uniform a

PLAN AND SECTION OF HAMBURG SHIP-TESTING TANK

section as possible without any abrupt changes. In order to insure the tank against settlement, which might occur due to the unstable conditions of the ground at the point where the excavation for the tank was made, the design of the tank was made unusually heavy as shown in the diagram.

To insure watertightness each construction joint was provided with a groove that later was filled with asphalt

or clay and the outer surface was covered with a layer of felt and asphalt. Upon completion the interior of the tank received a carefully troweled surface. As far as possible the construction joints were placed at such intervals as to provide for expansion and contraction.

In order to keep weather conditions from affecting the tests a steel frame building with brick-filled walls was built over the entire length of the two tanks.

Steam Railroad Tracks in Paved Streets at Philadelphia

A NEW design of track for steam railroad lines in paved streets, adopted by the Department of Public Works at Philadelphia, Pa., has as its main features a 159-lb. 9-in. grooved girder rail and separate rail blocks instead of the usual cross ties, the gage of track being maintained by tie rods. About 5½ miles of this new track construction have been laid to carry slow-moving freight traffic. The rail is shown in Fig. 1 and the track construction in Fig. 2.

FIG. 1—GROOVED RAIL FOR STEAM RAILROAD TRACKS IN STREETS

FIG. 2—TRACK CONSTRUCTION IN PAVED STREETS

A 9-in. 143-lb. T-girder rail with flat head was used formerly for freight tracks in paved streets, but a more rigid section and a grooved head were considered desirable to stand the wear and traffic and also to permit of laying the paving close to the rail, thus affording a better surface for street vehicles. The form of groove adopted is such that the rail gives a good bearing for the wheels of such vehicles and facilitates their movement in turning out of the track.

A concrete base is used for the entire track area of main tracks and industrial connections, and it is found that the use of separate rail blocks or supports reduces repairs to the granite paving in the track area to a minimum. These blocks, which are of treated wood, are 7 x 9 in. in section and 24 in. long. The foundation is of 1:3:6 concrete and over the base of the rail is a filling of 1:4:8 concrete carrying the 1-in. cushion course of cement and sand upon which the granite blocks are laid. Grout filler is used for the paving and cement mortar is packed against the web of the rails.

Items in Cost of Pumping Water for Irrigation Use

Vital Operating Factors Necessary to Consider in Deciding on Construction Best Adapted for Securing Water Supply

By BARRY DIBBLE

Project Manager, U. S. Reclamation Service,
American Falls, Idaho

LOOKING forward to the future of irrigation development in the West it is apparent that the acreage which depends on pumps is sure to increase. Cheap gravity water supplies have all been used and other methods must be applied. Often pumps can properly be considered an alternative to long gravity canals, tunnels or other expensive features. Both from construction and operation standpoints they frequently can be proved the most economical and the most reliable solution of the problem. Each case involves many special conditions which must be considered from all angles before a decision is made on the construction best adapted for securing the water supply.

In the first place a large pumping plant supplying an extensive tract of land presents very different questions from a small unit which pumps water to a single farm or at most to a few neighboring farms. In this region electric drive or direct water-turbine drive are the only ones that need be considered for larger installations. Feasibility in these days is more a matter of cost than of mechanical limitations. Annual costs include fixed charges, power, supplies and repair parts and labor.

Fixed Charges—Interest will vary with the invest-

ment. It is often a large factor in determining feasibility, but the case is no different with a pumping plant than with canals or other parts of an irrigation system. When depreciation allowances are made they are assumed to provide against the day when large replacements will be necessary and to retire machinery that becomes obsolete through advances in the art. Within a few years after a plant is put in operation, replacements of apparatus begin and if the plant is well maintained the expenditures for this purpose largely offset the depreciation.

TABLE I—OPERATION AND MAINTENANCE COSTS PER ACRE IRRIGATED

Year	Pumping Division Minidoka Project	Average All Projects	Year	Pumping Division Minidoka Project	Average All Projects
1915	\$1.64	\$1.61	1919	\$2.63	\$2.46
1916	1.71	1.66	1920	2.77	2.95
1917	2.02	2.00	1921	2.52	2.55
1918	2.12	2.34	1922	1.85	2.12

Power—The cost of power is usually very important.

In recent years there has been such a growth in irrigation pumping that the valley in the load curves of western power companies has been changed into a summer peak. This means that generating machinery installed to carry the irrigation load is to some extent idle in the winter. The result is that a year's interest on the invested capital must be returned by the revenue secured during the irrigation season. As a consequence, in the future cheap power development must usually go along with pumping projects that involve high lifts. Not infrequently it happens that storage or diversion dams can be used at least for seasonal power and, by serving a double purpose, bring the first cost or investment within reach and greatly reduce the annual cost.

TABLE II. COST OF PUMPING PLANTS OPERATED BY THE U. S. RECLAMATION SERVICE DURING FISCAL YEAR 1921-22

G. E. D. C. — Gas-engine-driven centrifugal pump.
G. E. D. S. — Gas-engine-driven screw pump.

Good efficiencies can do much to keep down the power input to the pumping plant. There is little difficulty in obtaining electrical apparatus of a high standard. A great improvement has been made in recent years in the efficiency of pumps for both high and low lifts, but a high pump efficiency must be combined with a characteristic (or head-capacity curve) suited to local conditions.

Supplies and Repair Parts—While supplies and repair parts are usually a relatively small percentage of the annual cost they can by no means be disregarded. High efficiency means less wear and tear on working parts and hence results in a reduction of this item. Adequate supervision and frequent inspection can effect considerable saving and improve reliability.

Labor—The number of employees needed both for ordinary operation and for repairs can be controlled in large part by the selection of the machinery and by its arrangement. This factor is too often given scant consideration until the operating man comes on the ground, but if it is evaluated by capitalizing labor savings its importance will be better appreciated. If one large plant serves the project, then one man on a shift represents only a modest outlay (and there is little excuse for designing a plant to require more than one operator), but to keep constant attendance at small and scattered plants requires a large expenditure. In the latter case automatic devices to start, stop and protect the plant are well worth consideration.

That pumping does not necessarily cause increased cost is well illustrated on the Minidoka Project of the U. S. Reclamation Service where water is lifted to an average height of 70 ft. to irrigate 49,000 acres, of which 46,000 acres are actually irrigated. The topography made it necessary to build three stations, each lifting the water 30 ft. All the water (800 sec.-ft.) is pumped by the first station, 650 sec.-ft. by the second, and 430 sec.-ft. by the third. The highest canal is 90 ft. above the first intake. Over the period of years since 1915 the cost per acre irrigated under this system has not varied greatly from the average cost per acre on all the projects of the Reclamation Service (which cover over 1,000,000 acres), as Table I indicates.

These costs are for operation and maintenance only and do not include interest or depreciation allowances. Both columns are on the same basis. As the Minidoka system has been operated since 1909, replacements are now an annual necessity and are included in maintenance costs. In 1921 the cost chargeable to power generation and transmission and to pumping was 80c. per acre; in 1922 it was 69 cents.

It is impossible to fix any physical limit to the height at which irrigation pumping becomes prohibitive. The limit is determined by the cost—the annual cost as compared with the returns from the crops produced. If favorable conditions make for low costs or high yields the height pumped can be much higher than where the opposite conditions prevail.

About 150 pumping plants costing \$2,360,000 are operated for irrigation and drainage on the various projects of the U. S. Reclamation Service, lifting water against heads of from 2½ to 200 ft. In the various stations motive power is installed from 5- up to 2,760-hp. capacity. The combined requirements of the stations are 17,500 hp., and the annual consumption of the stations driven with electricity is more than 33,000,000 kw.-hr. An interesting compilation of the

operating costs of these stations is given in Table II. Results of operation of pumping plants vary widely, but it is convenient to use a common unit, and for this reason, the final column in the table shows the cost of raising an acre-foot (325,829 gal.) of water 1 ft. high.

Subgrade Results in the Pittsburg Road Tests

Extract from the report of highway research at Pittsburg, Calif., by Lloyd Aldrich, engineer in charge, and John B. Leonard, assistant engineer.

METHODS of constructing subgrade on adobe soil so reduced the objectionable features of this material that a reliable foundation for pavement resulted. This subgrade was not injured by water which filled the side ditches for three months. Rock ballast was less efficient than the earth subgrade.

The site of the test highway was a field in which the soil was a very obstinate black adobe. The ground sloped gently from the south to the north and to avoid variations of subgrade condition the entire subgrade was on fill. On the south side excavation was carried to 3 ft. inside borrow pits and the material was placed loosely outside; the fill for the entire track was then started approximately 3 ft. below finished subgrade elevation. The bottom soil was first plowed about 8 in. to produce a bond and layers of earth approximately 9 in. in thickness, loose, were successively placed from the borrow across the entire width of the roadway, and each layer was pulverized by using a disk harrow followed by a straight-tooth harrow and a Johnson scarifier. After pulverization was complete, a light spray of water was applied over each entire layer sufficient to moisten but not excessively wet the soil, and to aid in compacting it into a dense homogeneous mass. A 12-ton, 3-wheel road roller rolled each layer, and weak spots in the subgrade layers that developed were excavated, and refilled, and rolling continued. The compacted layers were approximately 6 in. thick and each was scarified with a Johnson scarifier for 2 in. to furnish a complete bond with the succeeding layer.

On this approximately completed subgrade, header boards were set true to line and grade and extending slightly below the surface. Then the material between was scarified to a depth of 6 in. by a Johnson scarifier. The surface was then graded with a Carr subgrade machine to an elevation approximately 1½ in. above subgrade. The surplus earth was temporarily placed on the shoulders. Then the subgrade was scarified to a 4-in. depth and water applied with a very light spray, after which the subgrade was immediately rolled from the edges inward. While still moist it was again cut with the subgrade machine to the correct elevation. Up to the time of laying concrete the subgrade was given a light sprinkling daily to prevent cracks forming. Where inverted curbs were involved in the design, excavations were made with pick and shovel.

The sub-base for Section A was especially prepared. After preparation of the subgrade as for all sections, sufficient soil was removed to provide for a layer of crushed rock 12 in. deep on the longitudinal center line, tapering to a thickness of 4 in. at the edges of the pavement and extending out 2 ft. onto the shoulders. The rock was placed in two layers and rolled, the bottom layer consisting of 1½-in. to 2½-in. rock and the top layer ½-in. to 1½-in. rock. After rolling and filling the depressions with small rock to bring the surface within 1 in. of the finished subgrade elevation, a layer of earth about 1½ in. thick was placed over the rock and rolled to final compression. The proper subgrade elevation was obtained in the usual way by cutting off a layer of earth with the Carr subgrade machine. The object of placing the soil on the rock was to provide a smooth surface upon which to deposit the concrete and not in any sense to be used as a binder. Rock fill drains were constructed to the borrow pits on each side of the pavement.

Results of Some Researches in Concrete

Abstracts of Papers Presented to the Annual Meeting of the American Society for Testing Materials—Accelerators for Concrete; Fatigue of Mortar, Curing Agents, Workability Tests, and the Behavior of Slag Aggregate

Effect of Accelerators on Concrete

DURING the past two years a sub-committee of Committee C-9 has conducted a co-operative series of tests on accelerators of the calcium chloride type. For some reason, or perhaps several reasons, tests of accelerators do not always give as uniform results as other kinds of tests, and the general conclusions of the report should not be assumed to hold for every possible combination of accelerators and concrete materials. On the other hand, it seems safe to assume that an accelerator which adds to the concrete mixture 2 or 3 per cent (by weight of the cement) of calcium chloride will in the very great majority of cases markedly increase the rate of early hardening.

The tests show that 2 to 4 per cent additions to 1:2½ mortars increase 2-day strength from 40 to 70 per cent, 7 day from 15 to 32 per cent, 28 day from 1 to 18 per cent and 3 months and one year from 2 to 10 per cent.

The individual results show a very wide range and numerous inconsistencies. However, the averages of all the results seem to establish the general conclusion that the beneficial effects of the accelerators are confined to the early age under the prescribed laboratory conditions of curing and storage. Under these conditions the effect of the calcium chloride is to accelerate the hydration of the cement markedly during the first few days, but the resulting gain in strength largely disappears at the 28-day period and thereafter. The relative strengths of the mortars containing the accelerators after the 28-day period are slightly higher than those of the concretes and of the plain mortars for the later periods.

The marked differences in the results reported from the different laboratories indicate that different brands of cement respond in different degree to the accelerators but the inconsistencies in the results are sufficiently numerous to warn against drawing any positive conclusions in this respect. While the action of calcium chloride on cement is not well understood, it is to be presumed that it is effective in promoting the hydration of one or more of the main constituents of the cement, and as these constituents are known to exist in different proportions in different cements, and even in different lots of the same brand of cement, it should be anticipated that different brands or lots would respond in different degree to the action of accelerators.

In regard to the comparative effects of different accelerators, the data obtained in this investigation suggest that the acceleration of hardening is probably dependent either upon the proportion of calcium chloride to the cement, or the concentration of calcium chloride in the gaging liquid. A considerable amount of time was therefore given to an analysis of the complete data from three of the co-operating laboratories, in which the relative strengths were plotted against the two factors: ratio of anhydrous chloride to cement, and concentration of anhydrous chloride in the gaging water. Curves of the same type were obtained in both cases but the wide range of individual results made it impossible to determine to which of these two factors the relative strengths were more closely related. It would undoubtedly be of interest to know more than we do at the present time regarding the relation of quantity or strength of calcium chloride to the acceleration of the hardening of concrete, and in fact to know more about the action of calcium chloride on cement, but this information must come from a more comprehensive and carefully planned investigation. So far as the data from these tests can be interpreted, the different accelerators produce effects which are mainly dependent upon their calcium chloride content. It is not to be inferred, however, that the acceleration of hardening is directly proportional to quantity or concentration of calcium chloride, for a maximum effect upon the strength

of concrete exists on the average not much beyond the maximum concentrations employed in these tests.

In conclusion, the sub-committee would recommend that if further data were to be sought on the effects of accelerators, perhaps the information of greatest practical value would be forthcoming from their effects upon mortar or concrete at temperatures in the neighborhood of the freezing point, and also under conditions where wet curing is impracticable. Results indicate that calcium chloride is more effective under dry curing than under moist curing. It is important also that definite knowledge be obtained regarding the effect of accelerators upon the steel in reinforced concrete. Such meager information as is available at the present time indicates that when steel is completely embedded in dense concrete, the danger of serious corrosion from the chloride is negligible, but it is doubtful whether this statement applies to all types of reinforced-concrete construction under all conditions of exposure.

Fatigue of Mortar

BY R. B. CREPPS

Assistant Professor of Testing Materials,
Purdue University.

THIS PAPER describes in more detail the series of tests already outlined by Prof. W. K. Hatt in *Engineering News-Record*. Concrete beams are tested in reverse loaded as cantilevers mounted on a rigid column. The specimens were 1:2 mortars in 4x4-in. sections 30 in. long.

There is a progressive deformation in the extreme fibers until failure of the test specimen takes place. A straight line of constant slope relation is indicated up to 110,000 reversals of stress. At this point, four cracks appeared on the outermost fibers of the specimen, and the slope of the line changed. An additional 35,000 reversals of stress were necessary to produce complete failure. The critical point in the progressive deformation cycle is designated as the premature failure limit.

Rupture or failure of the bond occurs first on the extreme outer fibers where the deformation is a maximum. This action is progressive toward the center of the beam until complete failure is imminent. Continual progressive deformation of the outer fibers is significant of the fatigue element. Progressive deformation may occur in some cases for a certain number of reversals when it becomes evident from the flatness of the deformation curve that the material is showing no ill effects from repetitions of the load. The assumption is made that loads producing constant deformation are below the endurance limit or the safe working stress of the material.

Recovery Phenomenon—An interesting feature of the fatigue tests is that of the appreciable recovery during a period of rest of the strength of mortar undergoing a fatiguing action. It has been necessary each night to stop the machine and, as a result, the strength recovery phenomenon is clearly illustrated. A parallel action is common to many materials, such as, metals, wood, and soils when they are stressed beyond a safe limit. The amount of recovery in the case of cement mortar is directly proportional to the duration of the period of rest. It is to be noted that no recovery occurs after the premature failure limit has been attained.

During this series of tests it became necessary to stop the machine for five weeks, and as a result the effect of a prolonged rest period is clearly evident from the trend of the deformation curves. The degree of deformation following the rest period indicates that the beam had fully recovered from the initial overstressings. As these beams were five

months old, it is thought that the increase in strength due to age over the rest period exerted a minor influence upon the subsequent resistance of the mortar.

This phenomenon seems to indicate that the rate or number of intermittent applications of load ranging in intensity above the endurance limit would have considerable bearing upon the life of a concrete structure.

Summary—The purpose of the paper has not been to present finished data or to draw definite conclusions concerning the fatigue of mortar and concrete, but more to stimulate interest and discussion of the subject. There are, however, several indications of prominence which are emphasized by this investigation:

1. (a) 28 Day Tests, 12 Beams, 1:2 Mix.—Results of this series of tests indicate that no definite endurance limit between 40 and 60 per cent of that load required to break the beam under a single application can be assigned to cement mortar of this age.

(b) 4 Month Tests, 8 Beams, 1:2 Mix.—Results of this series of tests indicate that the endurance limit is approximately 50 to 55 per cent of the static load.

(c) 6 Month Tests, 6 Beams, 1:2 Mix.—Results of these tests indicate that the endurance limit is 54 to 55 per cent of the static breaking load.

2. The number of reversals of stress necessary to cause failure decreases in a proportion to the respective increase of the percentage of stress above the apparent endurance limit.

3. Stresses above the endurance limit cause continual progressive deformation.

4. Stresses below the endurance limit may cause progressive deformation within certain limits.

(In either 3 or 4, progressive deformation is not significant of permanent injury to the product unless actual rupture of the bond occurs on the extreme outermost fibers.)

5. The effect of a rest period indicates that the rate and number of intermittent applications of load ranging in intensity above the endurance limit would have considerable bearing upon the life of a concrete structure.

6. (a) The amount of recovery in strength in the case of cement mortar is directly proportional to the duration of the period of rest.

(b) Above the premature failure limit no appreciable recovery occurs.

Calcium Chloride as a Curing Agent and Accelerator

By H. F. CLEMMER and FRED BURGGRAF

Engineer of Materials, and Assistant Engineer of Materials,
Illinois Division of Highways

THIS PAPER reviews the investigations in the use of calcium chloride both as a curing agent and as an accelerator in the setting of concrete, conducted by the Illinois Division of Highways, the results of which have led to the adoption of both the external and internal usage of calcium chloride in concrete highway construction.

External Treatment—Over 500 concrete slabs, 8 x 12 x 30 in., were subjected to various surface treatments and tested for transverse strength. Cylinders, 6 x 12 in., were also made to serve as a check on the compressive strength of the concrete making up the transverse specimens. The same volumetric mix of 1:2:3½, which is the standard adopted by the state of Illinois for concrete highways, was used in all specimens. Portland cement was used in all cases and the aggregates consisted of sand and washed limestone which passed all state specifications.

As Illinois was interested primarily in securing a satisfactory curing at the end of 28 days or earlier, more emphasis was placed on these short-time tests than on 60- or 90-day specimens. For the purpose of checking the strength of the untreated specimens at the older ages, a number of 60- and 90-day specimens were made. At the time of testing, the specimens were removed from their forms and

broken in a universal testing machine with the treated side in tension. The modulus of rupture was then computed and the variation in strengths considered as a measure of the completeness of curing.

[Three series are reported, of which the first is typical.]

The accompanying diagram contains a graphical comparison of the results of the various curing methods as indicated by the moduli of rupture of the specimens in Series 1, the results shown being the average of 11 specimens. As the curing of concrete with 2 in. of dirt wet for 14 days has been considered by this state a satisfactory method of curing, the specimens cured under this method have been regarded as 100 per cent cured and the results obtained by other methods taken as a percentage of this.

COMPARISONS OF EXTERNAL TREATMENT OF
CONCRETE WITH CALCIUM CHLORIDE
Strength of Specimens Cured with 2 in. Dirt, Wet 14 Days,
Taken as 100 Per Cent Cured. Each Result Is the
Average of 11 Specimens. Age 28 Days.

As shown in the figure, only those specimens which received no treatment showed a strength less than 100 per cent, while the specimens cured with 3 lb. per sq. yd. of calcium chloride indicate the maximum of 116.9 per cent curing. Those slabs cured with 1 lb. per sq. yd. of calcium chloride also show a high degree of curing.

The early strength obtained with using calcium chloride curing would indicate that a pavement could be opened for traffic at the end of 14 days, whereas under the old method of curing it was felt unsafe to subject a pavement to traffic in any less time than 30 days. The results obtained from the specimens which were treated with calcium chloride that was removed some hours later illustrate that at the end of 28 days, proper curing has taken place. In other words, if the calcium chloride remains on the concrete for a period of 24 hours, its removal will not affect the curing of the concrete. Later tests in this regard illustrate that even less time than 24 hours was required for calcium chloride to properly cure concrete.

A brown surface stain developed on the specimens cured with magnesium calcium chloride. This discoloration of the concrete seems to result from the use of magnesium calcium chloride and for this reason this material as a curing agent is eliminated.

It is evident in the comparison of results on the speci-

mens cured in like manner, but having both a normal and oiled subgrade, that no benefit is derived from the oiled subgrade. In both the 14- and 28-day tests, less strength resulted from the specimens placed on the oiled subgrade than was obtained with the normal condition of subgrade.

A study was also made of the effects of concentrated and excessive amounts of calcium chloride on the surface of mortar briquettes. The proper distribution of this material is a constant source of trouble with the highway department and it was thought advisable to learn as far as possible in the laboratory the effects of too much calcium chloride on the surface of concrete. Consequently, a number of briquettes were made and were subjected to surface applications of calcium chloride up to what would amount to 10 lb. per sq.yd. of surface. A puffing up of the surface was noticed with the result that a deadened concrete was developed. The danger of a like condition developing in a pavement surface is seen when, in cases where moisture is present in the calcium chloride drums, the salt has a tendency to lump into pieces of considerable size. When these pieces are larger than the size of an egg, their use should not be allowed until they are broken up, since injurious effects of uneven application of the salt will result.

Though the exact action which takes place in the concrete when a surface application of calcium chloride is applied is not known, a theory has been advanced which appears to be the most logical of any yet advanced. The great amount of work done with calcium chloride by the Illinois highway department corroborates so far as is known the theory which is as follows:

The hygroscopic properties of calcium chloride are responsible almost entirely for the value of the material as a curing agent. Though the calcium chloride may not obtain sufficient moisture from the air to satisfy this property, its presence on the surface of a concrete specimen which contains more moisture than the air, attracts moisture to aid in the dissolution. This action of the moisture being drawn to the surface of the specimen leaves minute channels, which, after the complete dissolution of the chemical, affords passages for the calcium chloride solution to penetrate the surface, thus giving it access to more cement particles and causing more complete hydration in a shorter time. This quick hydration and decomposition of the lime compounds of the cement particles on the surface causes an impervious layer which prevents drying of the concrete.

An understanding as to the reason for approximately as great a strength resulting in 14 days from the use of calcium chloride as that resulting in 28 days when curing with wet dirt is apparent when the two methods of curing are considered. In curing with wetted dirt, the increase in strength and hardness of the concrete is due to the ever present moisture which gradually hydrates and decomposes more of the lime compounds. In curing with calcium chloride, the chemical acts as an accelerator in hastening the hydration and inter-reaction of the cement particles on and immediately below the surface.

Rules for Application of CaCl_2 .—As a direct result of the investigation in curing concrete, the Illinois highway department is now permitting the use of calcium chloride in curing state highways. In order to reduce the cost of curing by this method, the amount used has been specified as 2½ lb. per sq.yd. of surface, this amount being considered as effective as the 3 lb. which was employed in the tests. In order to acquaint the engineers and contractors with the use of the material, a circular has been issued which reads:

"Calcium chloride may be used in connection with curing of pavements, taking the place of the usual curing with earth and water, or the curing with water by what is known as the "ponding method." Two and one-half pounds of the flaked or granular material (the flaked is preferred as it is more easily distributed and less easily removed by wind or rain) shall be applied to each square yard of pavement and it shall be distributed uniformly over the surface of the finished pavement by means of a mechanical drilling device or by the use of shovels and long-handled brooms. The material shall not be spread upon the pavement until the latter has thoroughly set—ordinarily from six to eight

hours time after the particular pavement has been laid

"Calcium chloride shall not be applied during rains and experiments have definitely determined that if a rain follows the placing of the calcium chloride after a period of two or three hours there will have been enough absorption of the calcium chloride by the new pavement preceding the rain so that there will not be required additional applications of the material.

"Although the water line for curing of pavements with water may be omitted where central mixing plants are operated and calcium chloride is used in curing; nevertheless the general specifications with regard to wetting of subgrade and the general specifications with regard to placing of burlap on the freshly deposited concrete and the wetting of burlap shall be strictly enforced. The use of calcium chloride for wetting the subgrade will not be permitted. When calcium chloride is used in curing, the sides of the concrete pavement shall be banked with earth as soon as the forms are removed."

Internal Treatments.—The investigations in internal treatment with calcium chloride was mainly in reference to the effect on setting time, the strength in low temperatures, the internal temperatures, and the variable strengths obtained with the same percentage of material in different brands of standard cements. Some work was begun on determining the percentage of hydration caused by the calcium chloride but sufficient data are not at hand for a comprehensive discussion of the experiment at this time, although a short outline of the work will be given. Both physical and chemical tests were included in this investigation. A uniform incorporation of calcium chloride was obtained by dissolving the chemical in the gaging water before the water was placed in the mixer.

It was observed that the setting time of the specimens at both temperatures is reduced through the addition of calcium chloride. The specimens containing 3 per cent by weight of calcium chloride indicate the best results as far as securing the quickest set is concerned.

The investigations conducted with concrete specimens poured in low temperatures merely illustrated the fact that even the presence of a large percentage of calcium chloride will not allow the placing of concrete in freezing temperatures without some provision being made to protect the concrete from the cold weather. Probably the most striking feature of this experiment was the failure of the specimens to gain strength past the 14-day period.

Considerable time was spent on the study of the variation of internal temperatures caused by the incorporation of the different amounts of calcium chloride. It was found that a greater heat is generated by the specimens containing the larger percentage of calcium chloride.

It has been fairly well established that various brands of standard cements hydrate four to five times as fast as others when incorporated with a constant solution of calcium chloride.

Rules for Inclusion of CaCl_2 .—The results secured in these investigations were such that the Illinois Division of Highways was satisfied that calcium chloride could be incorporated in concrete to advantage under certain conditions. Consequently, its usage is allowed in cold weather construction upon the permission of the engineer in charge of the job. To insure the proper supervision, the department has issued a circular explaining how this material must be used. The circular reads as follows:

"The department will permit the use of calcium chloride in the concrete mix for pavement construction during cold weather. When used, the solid, granulated, flaked, or powdered materials shall be thoroughly dissolved in water. It is recommended that the proper amount of calcium chloride solution should enter the mixer drum just before the water is added to mix the aggregates, or the solution may be added direct to the stone or sand when in the skip.

"When used in the pavement work, not more than two per cent by weight of the cement shall be used.

"Calcium chloride should not be used in a pavement that crosses an electric railroad, but its use should be discontinued approximately one quarter of a mile from the elec-

trical railroad crossing. There is no objection to using the material when the highway parallels an electric line. Calcium chloride shall not be used in pavements which are reinforced.

"It is not definitely known at what temperature concrete will freeze when the two per cent of calcium chloride is mixed with the concrete and it will, therefore, be necessary to arrange to cover the pavement with loose straw or earth as soon as it has taken sufficient set to prevent marred of the surface. In other words, calcium chloride hastens the setting of the concrete but is in no sense a protective. It makes possible an earlier application of a straw or earth covering.

"Due to its action on reinforcing steel, calcium chloride shall not be used in bridge or culvert construction; therefore, the usual precautions should be taken when placing concrete in culverts and bridge during temperatures around freezing point.

"All material should be purchased with the guarantee that it contains from 70 to 75 per cent calcium chloride and before using samples should be submitted to the testing laboratory, as in the case of any other materials."

A New Test for the Workability of Concrete

J. C. PEARSON AND F. A. HITCHCOCK

U. S. Bureau of Standards, Washington, D. C.

IT IS NOT easy to define the terms "workability," "plasticity," "consistency," etc., as applied to concrete mixtures. Some authorities use these terms more or less synonymously; others prefer to distinguish between workability and consistency, considering the latter as a property directly related to water content and measurable by the slump, flow, and other tests, whereas workability is regarded as more intrinsically a characteristic of a given mixture, dependent not only on the water content, but essentially upon the other ingredients of the mixture. We incline to this latter view, and without attempting to give an exact definition of workability, we consider one concrete mixture more workable than another when the process of mixing, handling and placing are accomplished with less effort in the one case than in the other. The direct quantitative measurement of this effort, for example, in placing a concrete mixture in any sort of a form or mold is a very difficult thing, chiefly because there is no telling when one arrives at a definite condition that may be taken as a stopping point in the placing operation. We have made many attempts to measure the workability of various concrete mixtures in this way, but thus far without success.

During the past two or three years we have given a great deal of thought to the possibilities of measuring the workability of concrete by some indirect method and eventually came to the penetration test which is the subject of this paper.

Apparatus.—The apparatus used in the penetration test is shown in the drawing. *M* is a 6 x 12-in. pipe mold with a watertight bottom, fitted with slotted lugs, *L*, by means of which the mold is fastened to the small drop table *T*. The latter is in reality an ordinary flow table with a special

top carrying two clamp nuts, *B*, which engage the lugs, *L*, of the pipe mold. The table top can be raised and dropped through a height of $\frac{1}{2}$ in. by means of a cam on the end of the shaft *P*. Fitting the top of the pipe mold closely is a detachable brass spider *F* carrying a fixed sleeve *S*, which, when the frame is in position on top of the mold, is exactly in alignment with the axis of the mold. The sleeve *S* is $\frac{3}{4}$ in. inside diameter and 6 in. long. A steel rod, *R*, $\frac{1}{4}$ in. diameter, 20 in. long, weighing 1100 g. completes the apparatus. The lower end of the rod *R* is hemispherical, and the upper portion is graduated in 0.1 in. in such manner as to read directly the depth of the lower end below the top of the mold when inserted in the sleeve *S*.

Method of Test.—The mold *M* with the brass spider *F* clamped to the top is fastened to the table by means of the clamp nuts. The batch of concrete to be tested is scooped into *M* until the latter is filled to the brim. No attempt is made to puddle the concrete into the mold, but a rod is used to spread the concrete uniformly as it falls from the scoop. After the mold is filled, the table top is raised and dropped a given number of times to subject the concrete to a definite amount of compacting force. Our practice throughout has been to give the concrete thirty $\frac{1}{2}$ -in. drops. At the completion of the preliminary jolting or settling, the rod *R* is inserted in the sleeve *S* and lowered gently into the concrete until it comes to rest under its own weight. The table is then raised and dropped, and from the force of the impact the rod penetrates a certain distance into the concrete, indicated by the reading of the scale. The impacts are repeated and the successive penetrations of the rod are noted until the latter has reached nearly to the bottom of the mold. In practically all of our tests the penetration has been carried to a depth of 11 in.

It is quite obvious that different mixtures should show different resistances to the penetration of the rod, the more plastic mixtures allowing the rod to penetrate readily, the harsher mixes offering high resistance. The property that we were admittedly trying to measure was the tendency of a mixture to pack under a definite amount of settling or compacting. This we seemed to have accomplished, judging from the results of a considerable number of preliminary experiments, but a more complete interpretation was lacking. It was primarily to furnish an interpretation of this test that the present investigation was undertaken; incidentally the investigation was so planned as to contribute some interesting information regarding the effects of certain powdered admixtures.

Conclusions.—The penetration test described in this paper is the first worthwhile solution of the problem of measuring the workability of concrete which the authors have found in a research extending over a period of several years. As used in this investigation, the test is lacking in desirable precision; it furnishes a measurement of workability in arbitrary units only, and it is not applicable to the entire range of concrete mixtures. On the other hand, these faults can probably be eliminated, and even in its present stage of development, its indications seem correct and in accord with the best judgment of a number of experienced operators. This is true if workability is defined as that property of a concrete mixture upon which depends the amount of work required to handle and place the concrete uniformly, under the ordinary conditions of use.

As indicated by the penetration test, the workability of a concrete mixture seems to depend upon two factors, segregation and lubrication. It appears that both of these factors can be controlled by a suitable selection of ingredients, an increasingly fine aggregate reducing the segregation, and powdered admixtures reducing segregation and promoting lubrication. This increase in workability brought about by the use of finely divided admixtures seems to be proportional to the fineness as measured by the completeness or extent of dispersion of the material in the mixture. Thus, celite was found to have greater effect in improving the workability of concrete mixtures than kaolin, and kaolin a greater effect than hydrated lime.

In studying the relation between workability and consistency, as indicated by the penetration and flow tests,

respectively, the interesting conclusion was reached that workability depends more on the character and proportions of the solid ingredients in the concrete than on the amount of mixing water used. Although this conclusion may appear open to question, the authors believe it to be correct, and they also believe that false notions in regard to chuting operations. The facility with which concrete flows down a chute is probably dependent both upon workability and water, the effect of the latter predominating in the over-wet mixes. Whatever the facts may be, the indications of the penetration test substantiate the authors' opinion that there is no premium upon, and rarely an excuse for, employing a consistency higher than that giving the maximum workability obtained in these tests.

Under damp storage conditions, small quantities of admixtures generally increase the strength of lean mixtures, even though they require an increase in the amount of mixing water for a given consistency. The richer mixtures under the same conditions suffer a slight loss in strength. It is important, however, that further work be done to establish the effects of admixtures under drying conditions, where it is quite probable that strength, as well as workability, will be benefited. It is important also that further work on the subject include studies of the relative yield and shrinkage of concretes with and without admixtures, since these factors must be taken into account in determining the resultant effect in the finished product.

Blast-Furnace Slag as an Aggregate in Concrete

BY RAYMOND HARSCH

Junior Assistant Testing Engineer, U. S. Bureau of Public Works

THE U. S. Bureau of Public Roads started an extensive investigation in the summer of 1919 to obtain information relative to blast-furnace slag as an aggregate in concrete. This investigation consisted in obtaining plant data from the field inspection of about thirty crushing and screening plants which were at that time producing slag in commercial sizes.

In these tests, everything was held constant except the coarse aggregate. This varied from the very porous, honey-combed material produced by some plants to the black, glassy slags of others. The consistency of the mix was kept constant throughout the entire investigation. A slump of 1 in., corresponding to a flow of 160, was used. All results shown in the table are averages of tests on 3 to 5 specimens made and tested on different days and are the results of the compression and wear tests outlined above. These are represented by the part of the table down to and including limestone from Plant L. The tests on slag from Plants A, B, and C were made to determine the effect of maximum size of coarse aggregate.

Comparing the results of compression tests on concrete containing coarse aggregate from Plants Nos. 1 to 30 with those containing gravel and limestone, the highest strength obtained was 3656 lb. per square inch with slag aggregate, and the lowest 2809 using Potomac River gravel. The lowest strength of the slag concrete is 2906, which represents a high-silica, low-lime slag of glassy texture. The strength of limestone concrete is practically equal to the average strength of the slag concrete. The results of the wear tests show a lower percentage of wear for slag concrete than for either gravel or limestone. The differences, however, are small in most instances, and the test does not warrant any specific conclusion other than the fact that the slag concrete is as satisfactory as gravel or limestone concrete when tested by the Talbot-Jones rattle.

The lower part of the table contains results of tests on slag, gravel, and limestone concrete, when the variable was the maximum size of the coarse aggregate used. Group A refers to 1- to 2-in. aggregate, B is 1 to 1 in., and C from 1 to 1 in., all being proportioned between the sieves in amounts necessary to give a straight-line grading. The results seem to indicate that the 1- to 1-in. slag and lime-

stone make the strongest concrete, while the reverse is true for the gravel used. The slag shows a strength equal to that of limestone and superior to the gravel in every case.

As in the preceding results, less wear was found for the slag concrete than for the concrete containing either gravel or limestone. The wear tests results show the strongest slag concrete to have a greater loss in wear than the weaker concrete. The 1- to 1-in. slag concrete (the strongest slag concrete), however, still shows less loss than either the gravel or limestone concrete of any sizes of aggregate.

Wear Investigation—An investigation of the suitability of many doubtful aggregates has been in progress for some

time, consisting of circular track wear tests. The results of tests on the control specimens, made in connection with this investigation, throw some additional light on the relative value of slag as an aggregate in concretes. At the time the test sections of this experimental pavement were placed, three compression cylinders, three Talbot-Jones wear blocks and two 6 by 8 by 48-in. plain concrete beams were molded for each type of surface.

These results bear out the conclusions derived from the other investigations. They show slag concrete to be superior to the gravel concrete and also to the limestone concrete used in these compression and transverse-bending tests. Slag concrete wear blocks showed a lower percentage of wear than either the limestone or gravel except in the case of Section 1.

Attention is directed to the result of tests of a blast-furnace slag which had been hand picked from the lightest commercial slag available. In selecting this material, only the honey-combed pieces were included. The unit weight was only 56 lb. per cu. ft. when the material was uniformly graded from 1 to 1 in. This represents the type of slag which is the cause of most of the unfavorable comment regarding its use as an aggregate in the wearing surface of concrete pavements. An analysis of the test results on this material shows that the strength and wearing quality is not greatly impaired by the lightness or porous nature of the aggregate.

Summary—The data presented do not indicate any new development in the knowledge about slag used in concrete. They merely represent the work of unbiased operators endeavoring to find the value of slag as compared to two other concrete aggregates, limestone and gravel.

Specimens have been made for testing at the age of one, two and five years. A series of corrosion tests have been planned to determine the relative corrosive effect of slag, gravel and limestone aggregates upon reinforcing steel.

The following general conclusions are interpreted from the data resulting from this investigation:

1. The unit weight of blast-furnace slag as produced commercially has little if any effect upon the structural strength or the wearing property of the resulting concrete.

2. A limit of 70 lb. per cubic foot would admit practically every well-graded crushed slag product.

3. The gravel used in these tests is one of accepted quality and is considered to be of average strength. The limestone used for comparison with the slag is somewhat superior to the average limestone used for concrete. The strength of all of the slag concretes exceeded that of the gravel concrete. The average strength of the slag concretes is equal to the strength of the limestone concrete.

4. Because of the excessive chipping at the edges of the wear blocks, the wear test is not considered a very favorable indication of the resistance of concrete to wear. It is a means of comparing the value of various types of concrete subjected to the action of the shot, and is interpreted as such by the author. On this assumption, the wear-resisting properties of slag concrete are equivalent to those of the limestone concrete and superior to those of gravel concrete tested in comparison.

5. The physical properties of the slag when tested by the usual rock tests do not seem to be an important factor in determining the quality of the concrete made with slag as the coarse aggregate.

Possibilities in Engineering Society Co-operation

**President of American Society of Civil Engineers
Outlines His Views As To Methods
of Getting Together**

From the Presidential Address of C. F. Loweth, President, American Society of Civil Engineers, at the Annual Convention, Chicago, July 11, 1923.

MUCH HAS BEEN said of late of co-operation of engineering societies as though it was something new. It is not new. There has always been a goodly degree of co-operation; however, the great increase in the number of such societies and the fact that many of them are so highly specialized has seemed to call for an increased co-operation and at the same time made it increasingly difficult to bring about.

The membership requirements of some societies stress most strongly technical qualifications; in fact, in some the technical qualifications are highly specialized, and are fully met by manufacturers and expert technicians. In others the outstanding qualifications for membership are those of professional attainments and in some of these professional attainments of a highly specialized nature; in still others, social or local affiliations are a large factor in membership qualifications. It must be obvious then that under such widely varying society ideals co-operation will necessarily be restricted to matters of common interest. These may be local or national affairs, may be purely technical matters, or be those of a professional character; in each case the incentive for co-operation will vary. The incentive and opportunity for co-operation depends therefore, in a very large degree, upon a common interest, the purposes and ideals of the several groups and equally so upon an approximate equality of ability for the furtherance of that common interest. With such a multiplicity of engineering societies as now exist, co-operative efforts, if unduly forced, will naturally tend to a compromise of essentials or

to the over-emphasis of many things of minor importance. In such case the danger would be to the societies of largest prestige and highest ideals.

This society has recently and for the third time, declined to join with certain others in an all-inclusive plan of engineering society co-operative work. There is ample evidence that these decisions have been based upon the plan of and not upon the spirit of co-operation. Clearly this is so, for the whole history of the society shows time and time again a deeply rooted disposition to co-operate fully and freely whenever there has been opportunity to do so effectively. At the present time there is a very large degree of co-operation amongst engineering organizations in technical matters. The extensive and very excellent work being done by the Engineering Standards Committee, which is sponsored by a number of the engineering societies and participated in by many of their members, is a co-operative effort of high order; the same is equally true of the excellent work of the Division of Engineering of the National Research Council. Much other technical activity is being fostered through the joint agencies of various engineering societies. It makes but little difference whether this is accomplished through temporary agencies, such as joint committees, or more permanent ones. The American Society for Testing Materials and the American Railway Engineering Association may be considered, in view of the fact that many of their members are also members of other less specialized societies as co-operative organizations by engineers. Effective co-operation calls for united effort and, equally at other times, requires that one party shall refrain from duplicating the activities of the other. The setting up of Engineering Foundation for the furtherance of research in engineering and of United Engineering Societies for the management of the joint property interests of the four large national societies, called by these acts the Founder Societies, are other notable instances of co-operation.

In other than technical matters co-operation has not progressed as far, although far from being negligible. In those matters pertaining to the services of the engineering profession to the country and those pertaining to the general welfare of the profession, there is room at this time for more concerted activity on the part of engineering organizations. Considering these in their broadest aspects, it would seem as if it was the especial obligation, and as well the privilege, of the large national societies, particularly those in which the professional qualifications for membership are the highest and which for these reasons have the prestige and wealth of personnel, leadership and funds beyond those of local or specialized societies, to undertake primarily and largely the burden of representing the engineering profession at large. In that case then the Founders Societies with other national organizations of approximately similar standing and character might profitably set up some agency through which they might co-operate as occasion requires.

Such an agency might well meet the following requirements: Its field of activity should be specific. It should have definite responsibility to its sponsors, yet with some freedom of initiation and action. It should be elastic enough to meet varying needs, to act promptly in emergencies, to enlist such aids as might be helpful. Its vision should be nation-wide and its organization such that the influences initiating its action should be no less broad. Its chief function should be largely to bring about concerted action of various organizations as their mutuality of interest and influence might make necessary, rather than to attempt to speak for them, and it should so function as to leave room for expression of minority opinion or qualified approval where unanimity could not be obtained except as a result of compromise. It should have no incentive to be active solely for the sake of activity. The dangers of a super-organization should be thoroughly guarded against by tying it closely to its sponsors, and it may well be that its organization could be composed of men serving automatically by virtue of their offices in the sponsoring societies.

Such an agency, by whatever name it may be called, in addition to being useful in co-operative efforts, would doubtless promote the welfare of each sponsoring society.

From Job and Office

Hints That Cut Cost and Time

For the Contractor and the Engineer

Reinforced-Concrete Patch on Pipe Elbow Withstands Heavy Wear

IN PLACING the concrete lining in a small tunnel around one end of Priest Dam, on the Hetch Hetchy project in California, it was most convenient to deliver the concrete by the pneumatic method through a 6-in. pipe. The pipe, however, had to pass down a vertical 50-ft. shaft and at the bottom make an abrupt 90-deg. turn to enter the tunnel. Under this condition the air pressure of 100 lb. per square inch used for delivery,

BEND IN 6-IN. PIPE REINFORCED WITH CONCRETE
This bend had given more than seven times the average life of unreinforced pipe and was still in service when the job was finished.

plus the effect of gravity, caused excessive wear on the sharp bend in the bottom of the shaft. In fact the wear was so great that standard pipe bent to make the 90-deg. turn within a length of about 8 ft. sometimes had to be renewed after eight hours of service and seldom lasted more than three shifts.

To overcome this excessive wear a special bend was made up with an 8-ft. length of pipe bent into a right-angle turn, as usual, but reinforced by a concrete block or patch cast around it for the purpose of continuing to withstand the wear after the pipe itself had worn through. The concrete was 6 in. thick, entirely encircled the pipe, and was reinforced with 1½-in. drill steel bent to parallel the curve of the pipe. This steel was wired together and placed in the form with the pipe before the concrete was poured. The total weight of the 8-ft. pipe elbow and the patch which was cast around it was about 800 lb.

The special bend made in this way, and shown in the accompanying photograph, served continuously for the remaining 21 shifts required to complete the job. When the pipe line was dismantled, inspection of the special elbow showed that the wear had gone through the pipe and also entirely through the 1½-in. drill steel but had not yet worn through the surrounding concrete.

The tunnel lining work was done under the direction of W. F. Webb, president of the Universal Concrete Gun Co.

Suspended Structure Carries Sanitary Sewer Over Stream

BY J. C. KEELEY
Paducah, Kentucky

IN PLANNING the \$1,300,000 sewer program in Paducah, Kentucky, half of which is now under construction, it became necessary, in order to serve certain territory, to cross a stream, known as Island Creek, with a small sanitary sewer, the point of crossing being about 500 ft. upstream from its junction with the Tennessee River.

Due to long periods of high backwater from this river, during which an inverted siphon would be submerged to a depth of 30 ft., it was decided to effect a crossing with an overhead structure, rather than an inverted siphon, as flow through the latter would be seriously retarded and cleaning rendered difficult; the danger of destruction to the overhead, or suspended, structure by floods in the creek is considered slight, owing to the small watershed of the creek and its large channel so near the Tennessee River. The floods in the creek do not reach the height of the sewer except when the river is high; and, at such time, the current is diffused and reduced because of its expanse over a wider channel. The danger due to ice is also slight, as ice of sufficient thickness to endanger the structure does not form in this section. No serious flow of drift need be expected.

The crossing was built of 18-in. cast-iron pipe—in 12-ft. lengths, weighing 110 lb. per foot—carried on reinforced piers on the approach and over the channel suspended by steel members swung from the floor over the existing concrete arch bridge.

Piers of reinforced concrete to carry the approaches were built on 12-ft. centers, the upper portion being shaped to fit the lower half of the pipe.

Five structural steel hangers were used to suspend the sewer over the main creek channel. Each hanger was built of two 6-in. x 6-in. x ¾-in. angles, riveted back to back and bolted to the under side of the bridge floor with three 1-in. bolts; lateral braces to the hanger, made of 6-in. x 4-in. x ¾-in. angles bolted to the hanger near the bottom and to a 3-in. x 6-in. angle clamped around the arch ring, served to stiffen the structure and to provide additional support. Holes for the 1-in. bolts were drilled through the bridge floor from the roadway with an air drill; and a cable, lowered through one of the holes and operated by a derrick on the roadway above, hoisted the hangers into place, the hangers having been previously floated into position on a scow. The lateral braces were erected by means of a scaffold mounted on the scow.

After all the hangers were in place, the 15-in., 33-lb. channel was floated into position on the scow, raised and bolted to the hangers. The pipe was then floated on the scow into position, raised and suspended by bolts to the hangers and to the channel. The individual pipes, however, were not drawn fully into position until

HANGERS, BOLTED TO BRIDGE FLOOR, CARRY SEWER

all the pipes were assembled; after which the joints were calked with lead wool. After the calking was completed, the sewer line was drawn into final position by taking up on the nuts on the U-bolts.

The work above described is a part of the \$620,000 sewer construction now being done by the city of Paducah, Ky., the E. R. Harding Co. of Racine, Wis., being the contractor. Design and engineering supervision is being done through the office of the Department of Public Works of Paducah, of which Henry A. Pulliam is commissioner and chief engineer.

Cost of Cleaning Ballast by Machine and Hand; Pennsylvania R.R.

A WORK-TRAIN outfit used for cleaning stone ballast on the Western Pennsylvania division of the Pennsylvania R.R. consists of a locomotive, a flat car with 20-ton ditcher or revolving crane handling a grab bucket, a gondola car with a fixed inclined screen, and cabooses for the train crew and cleaning gang. A ballast cleaning train is shown in Fig. 1, but the train is sometimes made up with two or three ditchers and screens.

For the one-unit train, a gang of twenty laborers with a foreman works ahead of the train to remove the ballast between the ties, piling it in the center ditch to be picked up by the bucket, which also excavates the ballast outside of the track. With the train there are the operator and fireman on the ditcher, two laborers, the locomotive engineer and fireman, the conductor and a brakeman, making about twenty-nine men.

A $\frac{3}{4}$ -, 1- or 1-yd. grab bucket is used, according to the distance between track centers. It is fitted with teeth to tear up the compacted ballast to a depth of about 20 in. below base of rail. The quantity of ballast

averages 1.07 cu.yd. per yard of single track. No new material is added when the cleaned ballast is put back.

A woven screen may be used, of $\frac{1}{2}$ -in. rods spaced $1\frac{1}{2}$ in. c. to c., or a 1-in. plate screen punched with holes $1\frac{1}{2}$ in. square and $\frac{1}{2}$ in. apart, the holes in alternate rows being staggered. As shown in Fig. 2, the screen frame is 9 ft. wide and 11 $\frac{1}{2}$ ft. high, with its lower end pivoted to a horizontal base frame which rests upon the sides of the car and has a hinged support or back leg to support the screen in its inclined position. This base frame is clamped to the car.

The screen itself tapers from full width at top to 27 in. at the bottom, each side being formed by a 3x3-in. angle and 12-in. upstanding plate riveted upon the frame. At the bottom is a steel hood delivering the cleaned stone to an inclined chute which is hung along the side of the car (see Fig. 1) and deposits the stone just outside the ties, ready to be thrown back into place with forks. The dirt which falls through

FIG. 1—BALLAST CLEANING TRAIN

At left, train with ditcher and screen. At right, bucket picking up old ballast and chute delivering cleaned stone from screen to track.

the screen goes into the car and the screen is shifted along as the car fills.

The ballast train on one track handles the ballast of the adjacent track and must keep clear of regular trains. Extra trains get orders to look out for the ballast train. A portable telephone outfit enables the conductor to keep informed as to train movements and thus avoid unnecessary delays in getting clear of trains which are late. As a rule a two- or three-mile stretch of line between interlocking plants is given up to the ballast train. The actual working time averages from three to five hours per day, except where special arrangements are made for exclusive use of the track. In length of track cleaned per day, the maximum record is 3,455 ft. with one ditcher in 6 hr. 50 min. working time, the dirt screened filling five gondola cars. Other records include 1,320 ft. for one unit, 2,100 ft. for two units and 2,000 ft. for three units in one train.

Cost of Ballast Cleaning—In the comparison of cost of cleaning by machine and by hand, the cost is based on length of center ditch cleaned, as in both cases hand labor is employed for removing the ballast from cribs or between the ties and piling it in the center ditch. But the cost of machine work includes the screening of this extra ballast, while that of hand work is for the ballast in center ditch only. The figures in the accompanying table are for three ditchers and screens in one train and for an 8-hour day.

In a test for cost of cleaning ballast by hand, the men were required to clean to the same depth that is cleaned by the machine, 10 to 12 in. below the bottom

COST OF CLEANING BALLAST BY MACHINE: P. R. R.

Train Service		
Engine service, including oil, fuel, etc.,	9 $\frac{1}{2}$ hr. @ \$4.59	\$44.75
1 Engineer,	9 $\frac{1}{2}$ hr. @ 0.86 (\$1.29)*	9.14
1 Fireman,	9 $\frac{1}{2}$ hr. @ 0.95 (0.94)*	9.69
1 Conductor,	9 $\frac{1}{2}$ hr. @ 0.725 (1.0875)*	7.16
2 Brakemen, each,	9 $\frac{1}{2}$ hr. @ 0.56 (0.84)*	11.06
		\$78.80
Ditcher expense for three-ditcher unit.		
1 Ditcher foreman,	8 hr. @ \$0.628 per hr.	\$5.02
3 Ditcher engineers, each,	8 hr. @ 0.957 per hr.	4.82
3 Ditcher firemen, each,	8 hr. @ 0.506 per hr.	12.90
9 Ditcher laborers, each,	8 hr. @ 0.37 per hr.	26.64
Cost of repairs, fuel, oil, etc., each,	8 hr. @ 1.00 per hr.	25.50
Depreciation	8 hr. @ 0.75 per hr.	19.12
Three-unit ditcher expense.		\$94.00
Train service		78.80
Total cost to clean 3,000 lin.ft.,		\$172.80
or cost per linear foot		0.0576
* Pay $\frac{1}{2}$ time after eight hours.		

of the ties, and to dispose of the dirt over the bank about 20 ft. away. The labor used was exceptionally good and the men worked hard with the knowledge that the job had a special significance. The average per man was 26 ft. of center ditch (9-hour day). Cost per linear foot, 14.6c., as compared with 5.76c. for the machine work.

It is pointed out that in making comparisons the fact should be kept in mind that the machine cleaning is not affected by rain, extreme heat and other weather conditions that affect the efficiency of labor. Another decided advantage in machine cleaning is that the long digging teeth of the bucket tear up the "cleaning floor"

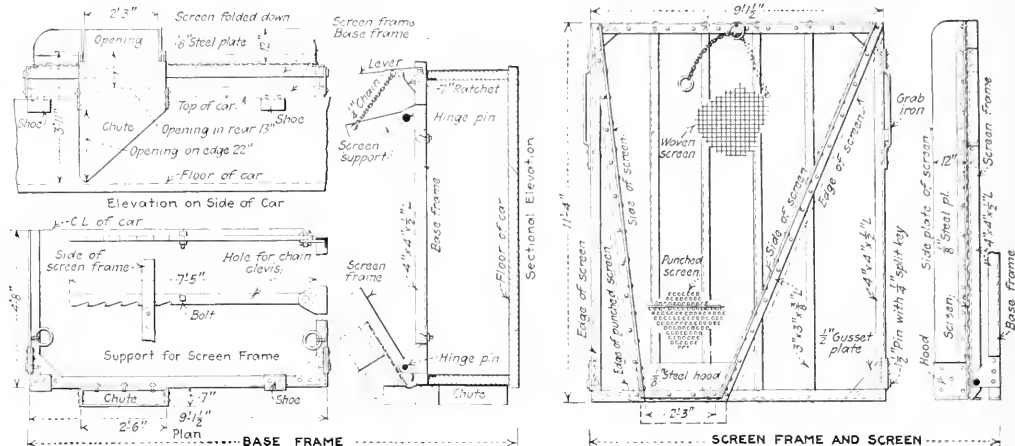

FIG. 2—FOLDING SCREEN FOR CLEANING BALLAST

at least 6 or 7 in. below the depth actually cleaned. The term "cleaning floor" is given to the bottom of the compacted mass of dirt and ballast that the trackmen shovel and fork over. This floor is gradually built up by successive cleaning and is objectionable in that it holds water and prevents it from draining away. This method of handling the cleaning of ballast on a busy main line was planned under the direction of Robert Faries, division engineer, Pennsylvania R.R., Pittsburgh, Pa.

Importance of Intercepting Ditches on Highway Construction

By F. M. BALSLEY

Engineer-Inspector, Wisconsin Highway Commission

IN THE planning of road projects it is believed that not enough attention is paid to the necessity of installing intercepting ditches above the top of the back slopes in cuts and outside the toe of slopes where the ground slopes toward the fill. This is particularly true in side-hill construction where there is a considerable drainage area above the road. Practically all highway specifications call for a neat and smoothly trimmed back slope in the cuts. In order to preserve this neat appearance it is essential that all water from the area above the top of the cut be prevented from running down the face of these slopes.

The simplest means of preventing erosion is an intercepting ditch placed far enough from the top of the

From Job and Office Hints that Cut Cost and Time

slope to prevent the erosion of the ditch itself from caving the bank. Where the drainage area is not large we simply specify that one furrow shall be plowed from 4 to 10 ft. back of the slope stakes, turning the furrow toward the cut. It is not always necessary to clean out this ditch by hand, but it is essential to have the course of the furrow run in such a direction as to maintain as

near as possible an even grade all the way down the hillside. Where the slope is fairly even the ditch may be close to parallel to the top of the cut, but in rough ground, of course, this is not true.

This intercepting ditch should be cut immediately after the slope stakes are set, then the work is protected while it is under construction. In cases where farm fences interfere and it is necessary to cut the intercepting ditch inside the fence line, it has been found that it is fairly easy to convince the property owner that the ditch will be a protection to his property rather than a damage. If the erosion of the slopes is not headed off, eventually the banks will cave in and the fence will go with them.

Where fills are made on sloping ground it is essential that an intercepting ditch be cut beyond the toe of the slope to protect the fresh fill from being washed out by the first flood. Many of our contractors and county commissioners fail to protect their work in cases of this kind. One furrow at the right point will form a ditch that will protect the toe of the slope and prevent material from washing out.

The plan shows a special type of culvert and downspout that was designed to take care of the water from the intercepting ditch on Project 41 in Grant County, Wisconsin. In this case there was a large drainage area above the road and the slope of the hillside was extremely steep. The ditch was first plowed and the loosened material was removed with a slip scraper. The culverts were placed in such a position that it was pos-

From Job and Office

For Contractor and Engineer

sible to drain the intercepting ditch directly into the culverts, thereby relieving the road ditch from a large amount of water. The grade on the finished road is 7 per cent, and it can readily be seen that if the accumulated water from the road surface itself, plus the water from the side hill, were carried in the road ditch it would be impossible to maintain the road at anything

WING AND INTERCEPTING DITCH PROTECT ROAD SLOPE

like a reasonable cost because of the greater erosion that would take place.

The wing ditch shown in the accompanying plan runs to a point back of the inlet to the downspout and heads off water that would otherwise follow the downspout and wash out the fill that covers it. A recent visit to this project indicates that this installation will never cause any trouble and it has been giving excellent service for the last three years.

In making a survey in rough country the notes should indicate the points where an intercepting ditch will be required and information relative to the size of a ditch necessary to carry the water. The typical sections for the finished work should also show the installation of an intercepting ditch in the cut as well as the fill section. If the ditch is large bids can be asked for on a cubic-yard basis. Where a plowed ditch is sufficiently large bids should be asked for at so much per linear foot of ditch. In the state of Wisconsin, where we must maintain roads after they are constructed, the matter of protecting the work as it progresses is of the utmost importance. In spite of this fact, many of our engineers fail to realize that a cheap, easily constructed intercepting ditch will save many times its cost in maintenance thereafter.

Concrete Units for Station Platforms

HIGH platforms to replace low ones were required in the electrification of the suburban lines of the Buenos Aires Western Ry. at Buenos Aires, Argentina, and it was necessary that this work be done without interrupting traffic or inconveniencing passengers. To meet these conditions a type of reinforced-concrete unit construction was adopted, so that the units could be placed during the night, the platforms consisting of piers with cantilever tops carrying deck slabs, as shown in the accompanying drawing.

The piers, about 32 in. thick, are spaced 8 ft. c. to c.

and have a cantilever projection of 1 ft. 9 in. on the track side, thus affording a refuge for workmen; this arrangement also permits persons who might fall from the platform to roll clear of the track. Between the piers there is a solid fill having the track side sloped

UNIT CONSTRUCTION FOR HIGH PLATFORMS

and faced with concrete which ends in a drain or gutter. The slabs are 8x2.2 ft., with a thickness of 8 to 9 in. and are covered with a layer of asphalt.

In carrying out the work, portions of the low platform were removed to allow of placing the shallow footing for the piers the openings being covered before the next day's traffic began. The next night a work train with a supply of units was run to the station and

a 5-ton steam locomotive crane set the piers on the footings and then placed the slabs. In this way about 330 ft. of platform could be built in two nights, including the erection of temporary wooden handrails, steps and ramps. The finishing work was then done by day and night shifts. At the terminal station a temporary high platform for the suburban tracks was built on one of the low platforms by placing timber bents which were framed in advance and handled by the crane.

Truck Trailer Carrying Tools for Water-Works Emergencies

FOR serious emergencies the Detroit Water Department has a truck trailer with tool boxes filled with everything likely to be needed. The truck has rubber

TRAILER WITH FIVE BOXES FILLED WITH EMERGENCY TOOLS

Hints that Cut Cost and Time

Santa Fe Ry. Moves Six Bridge Spans 43 Ft. Endwise

SHIFTING five bridge spans simultaneously was accomplished by the Atchison, Topeka & Santa Fe Ry. in moving a six-span single-track deck-truss bridge 43 ft. lengthwise, in order to place the structure on new piers. The bridge in question crosses the Des Moines River near Dumas, Mo., and was built originally in 1887, but the superstructure was renewed in 1904. The 150-ft. deck truss spans are in good condition, but the stone masonry was found to be disintegrating badly. It was decided, therefore, to build new double-track piers on the same center line but east of the old piers, at a distance of two panel lengths of the trusses, or 42 ft. 11½ in., this distance giving the necessary working space to construct the new piers. Solid rock is found about 6 ft. below low-water level and there were no difficulties in the foundation or pier construction. The height from low water to base of rail is about 56 ft.

In order to make the change it was necessary to revamp the east truss span by cutting off one panel at each end, thus shortening this span 42 ft. 11½ in., after which this span was moved east to its final location, the intervening gap being filled in with falsework (Fig. 1). Between the old and new piers falsework was placed, as shown in Figs. 1 and 2, to carry the rollers for shifting the remaining five spans. The adjoining vertical end posts of the remaining five truss spans were fastened together by means of diaphragms and also securely

FIG. 1—MOVING TRUSS SPANS ON SANTA FE RY.

At top, west end of east span resting on new pier, with falsework at left closing gap in deck and between new and old piers. At bottom, upper-deck falsework removed and spans moving to right towards new pier.

From Job and Office

For Contractor and Engineer

tied with steel cables. The spans were jacked up, the shoes removed and a grillage of T-rails was installed, which carried the load directly to the roller nests, as shown in Fig. 2.

Two stationary hoisting engines were installed between the old east abutment and the first new pier, one on each side of the bridge; these operated the 14-in. hemp ropes, passing through two

FIG. 2—ROLLER NEST UNDER SPANS

6-sheave blocks which were used in moving the spans. After the spans were moved to the new piers, the gap at the west end was filled in with a 42-ft. deck girder span resting on the old remodeled west abutment and on a steel bent on the new west pier. The placing of the bent on the new pier and of the girder span on abutment and bent is shown in Fig. 3.

Actual moving of the spans occupied a little less than an hour, while traffic was blocked only 5½ hr. The entire work was planned and carried out under the

Barrel and Automobile License Plates Form Tar Cold Patch Mixer

BY JOHN S. CRANDELL

Consulting Engineer, The Barrett Co., New York.

A VERY simple form of mixer for making up tar cold patching aggregate is shown in the illustration herewith. It consists of a strong barrel with a door cut in one side and hinged so that it may be securely shut and latched. On the inside three old motor license plates are bolted so as to form blades to assist in churning the mix. The barrel is mounted on strong supports, and a substantial crank is attached to the axle on which

HOME-MADE DEVICE MIXES TAR COLD PATCH

the barrel revolves. One man can do the entire work of mixing, and can supply sufficient material to keep a small maintenance gang busy. Or, where there is maintenance patrol by single patrolmen, this simple mixer is all that is required to make up the daily batch.

This mixer has been in operation for a year, and the output has taken care of the needs of one patrol gang's section.

The apparatus illustrated could be improved by making it more substantial. A steel drum might be substituted for the wooden barrel, and a rigid support mounted on wheels so that the mixer might easily be moved from one location to another.

Fender Chains Protect Panama Lock

One of the chain fenders protecting the lock gates at the Gatun locks of the Panama Canal proved its value on May 25 when struck by a steamer. The following account is condensed from the *Panama Canal Record*:

The steamship "Hoven" in tying up at the Gatun locks, on arrival from Gatun Lake, struck the chain fender protecting the upper guard gate. It is estimated that the vessel was going approximately four miles an hour and it was stopped within 50 ft. The chains prevented a collision which might have resulted in serious damage to the vessel and the locks, as the water in the upper chamber was about 15 ft. lower than Gatun Lake. Both chain fender machines apparently worked satisfactorily as about thirty-five links were pulled out from one and forty-two from the other. The incident was caused by a misunderstanding of signals in the engine room. These fender chains are stretched across the lock chamber from near the tops of the walls. To allow a ship to pass, the chains are lowered into a recess in the side walls and lock floor. After the ship passes, they are raised again. The mechanism consists of a hydraulically-operated system of cylinders, so that 1 ft. movement by the cylinder accomplishes 4 ft. by the chain. When a pressure of more than 750 lb. to the square inch is exerted against the fender, the chain is paid out by an automatic release until the vessel stops.

FIG. 3—CLOSING GAP IN BRIDGE

At top, placing new steel bent on new pier carrying west end of last truss. At bottom, placing 42-ft. girder span to rest on abutment and steel bent.

direction of A. F. Robinson, bridge engineer of the Atchison, Topeka & Santa Fe Ry. System. The moving of the steel spans was done by the American Bridge Co., while the Missouri Valley Bridge & Iron Co. built the new substructure and removed the old piers.

Letters to the Editor

This department aims to be a forum for the discussion of the views of engineers and contractors. The range of interest should be as wide as possible. Contributors are, therefore, asked to make their letters short.

Safe Roadway Widths

Sir—In connection with the discussion on safe roadway widths, a point deserving attention is the tendency of automobile traffic to form a single lane in each direction, regardless of the width. This tendency does not occur in wide city streets; but on suburban and country roads, where the traffic is crowded, the impulse to drive in the middle of one's own half of the road seems to be almost impossible to overcome.

In theory, a suburban road 25 or 30 ft. wide ought to be good on holidays for two lanes of outgoing travel in the morning and for two lanes of homeward travel in the evening. I have never, however, seen this occur.

The principle reason for using a roadway width of more than 20 ft. is to make it easy for faster cars to overtake and pass slower ones. In *Engineering News-Record*, July 12, 1923, p. 74, is a letter by G. F. Schlesinger, urging the undesirability of roadways of 20-ft. width on the ground that they invite a third lane despite their insufficient width. I have never noticed any such tendency, but, on the contrary, I have often noticed the insufficiency of such a width for permitting a faster car to overtake and pass a slower car, especially a truck. To make the roadway so narrow as to force an overtaking car over to the left of the road may be good engineering, but it is exasperating to the driver on a winding road who finds himself compelled, sometimes for miles, to trail a car ahead which is just fast enough so that he cannot safely pass it within the visible distance.

Unless the shoulders are very smooth, drivers on main roads will seldom turn onto them to allow an overtaking car to pass. The writer's conclusion is that a roadway less than 20 ft. wide, and preferably 22, is not safe. This refers to the concrete or bituminized surface. The width over shoulders should be at least 30 ft., and the shoulders should be kept smooth and flush with the main surface.

Where one such road is insufficient for the traffic, two alternative routes are better than one wide road, on account of the tendency to drive in single lanes each way.

HERBERT L. TOWLE,
David Lupton's Sons.

Philadelphia, Pa., July 19, 1923.

The Bar to the Solution of the North Jersey Water-Supply Problem

Sir—The water-supply situation in northern New Jersey, commented on editorially in your issue of July 12, p. 46, suggests comparison of the way public water supplies have been handled in that section and in eastern Massachusetts.

More than 30 years ago, some cities and towns adjacent to Boston were situated, as regards their public water supplies, very much as are now situated the municipalities encircling Newark and Jersey City. For this district in Massachusetts there was created by legislative action a Metropolitan Water Commission of three members appointed by the governor. This board took over the water-supply works of Boston and acquired other water-supply property. It borrowed large sums of money, issuing bonds on the credit of the state as security. It built works ample for the purposes of supplying water to the Metropolitan District. It paid the interest on the money borrowed, and paid off the principal from the money received for the water furnished in wholesale lots, and at wholesale prices, delivered to the several municipalities to be supplied, Boston included. The commission, since merged with like district commissions for main sewerage and for parks, is still at work.

Nothing is simpler in general outline; nothing more effective, or economical. Each municipality attends to the details arising within its own borders, the commission selling water in wholesale quantities, delivered to each municipality, and furnishing the main channels by means of which it is again removed in a sanitary manner.

Why cannot precisely the same plan of operation be engrafted on the life of the municipalities of northern New Jersey? Why has it not long ago been done? Why is there a continuance from year to year of a dearth of ample sanitary public works in northern New Jersey, conceived, constructed, operated and paid for, in a sane manner? The answer may be found in a portion of Art. IV of the New Jersey constitution which reads: "The credit of the state shall not be directly or indirectly loaned in any case." Therefore, instead of having Commissioners with powers of initiative to construct and operate for them ample works of public, sanitary necessity, the inhabitants of northern New Jersey are put to it to get such works at all. As population increases, each little municipality becomes unable to properly care for these needs. The works then, and thereafter, needed, must be planned with a vision that extends far into the future, and far beyond the boundaries of any and of all these municipalities, and mayhap into other states than their own. Such planning must continue indefinitely, and the commissioners must have full powers of initiative and of condemnation.

Of what need any "Jerseyman" be afraid should a proposition be presented amending Art. IV to read: "Except for the construction, maintenance and operation of works of water supply and main drainage, to be owned by and operated for the sole benefit of the people, the credit of the state shall not be directly or indirectly loaned."

The existing prohibition was intended, so it is said, to prevent the legislature from extending state aid to works of private enterprise, conducted for private gain, as in the wild days of the Camden & Amboy and other railroad ventures. It should no longer stand in the way of the creation of sanitary works needed for the public good.

How many states of the Union have such a clause, as this of New Jersey, in their constitutions, it would require some study to determine. It is plain that no state should throttle the construction of needed sanitary public works in this manner. All states may, instead, well follow, in their metropolitan districts, the example of Massachusetts, since public sanitary works, comprehensive as to political subdivisions served and as to time of construction, must needs be built in the manner described or they will not be built at all.

This is said with full knowledge of the fact that New Jersey is helping build a monumental bridge to Pennsylvania and a vehicular tunnel to New York; has voted \$40,000,000 to build roads and has managed, by invoking the individual credits of some twenty towns, to go far toward completing a Passaic main sewerage scheme, while certain cities, acting singly have built commendable water-supply works. Roads, bridges, and tunnels can be estimated and provided for, by a single, lump-sum appropriation. It is doubtful if any one cognizant of all the facts would ever want to repeat the Passaic main sewerage mode of working under the sustenance of a lot of independent warring municipalities, forced to act as commercial partners.

A water supply for the communities of northern New Jersey is a piece of work whose practical problems must largely be met as they arise. With the constant increase of population on the territory under consideration, it is a work without end. It is the need of the greater part of the population of the whole state. And it should have the support of the legislation of the state, modeled upon the legislation of any state of the Union most favorable for the planning, construction, and operation of works supplying such a need. New Jersey should no longer be prevented by an antiquated clause in the constitution, designed for a wholly different purpose, from adopting the sole rational method for the procuring by the people of what the people must have to live.

CLEMENS HERSCHEL.

New York City, July 16, 1923.

News of the Week

CURRENT EVENTS IN THE CIVIL ENGINEERING AND CONTRACTING FIELDS

News Brevities

Contract for the Construction of a Dam and Power House at Island Portage on the Abitibi River on the power development project of the Hollinger Consolidated Gold Mines, of Porcupine, has been awarded by the company to Sir William Arrol, Ltd., of St. Catharines, Ont., and London. Plans call for the installation of equipment with a capacity of 25,000 hp.

Orders for 1,000 Freight Cars have been placed by the Canadian National and Canadian Pacific Railways, the cars to have a capacity of 60,000 lbs. and to be much larger than the ordinary freight cars. The orders are distributed among several companies. The Canadian Pacific cars are of various types and are to be built at the Angus shops of the company in Montreal.

Traffic Tests on the Bates Experimental road near Springfield, Ill., conducted for more than a year by the Illinois State Division of Highways were discontinued last week. Approximately 1,000,000 tons of traffic have been imposed on the road and the majority of sections have shown decisive failures. H. F. Clemmer, engineer of materials, suggests that those who care to view the results arrange a visit within a few days as the road will be turned over immediately to the contractor for reconstruction.

Bonds of the Canadian National Railways to the amount of \$22,500,000, bearing 5 per cent interest and guaranteed by the Dominion Government, will shortly be issued for the purpose of equipping the railways with the necessary rolling stock. Hon. W. S. Fielding, Canadian finance minister, has announced. The total cost of the equipment required is \$3,000,000, one-quarter of which is provided by the general appropriation made by Parliament for railway purposes. Equipment orders given for the railways owned or controlled by the government have since 1918 reached a total of about \$130,000,000.

Competitive Examinations of Applicants for cadet engineers to fill vacancies in the Coast Guard will be held in several of the large cities of the country, commencing Sept. 10, 1923. Applicants must be between 18 and 23 years of age at the time of the examination and successful candidates will report about three weeks later at Coast Guard Academy, New London, Conn. Cadet engineers are trained to become engineer officers; during training they receive the same pay and allowances as midshipmen in the navy and upon graduation, after three years at the academy, are commissioned as ensigns. Information as to the places of examination and further details may be obtained from The Commandant, U. S. Coast Guard, Washington, D. C.

St. Paul Votes \$5,500,000 Bonds for Water-Works and Sewers

Bonds totaling \$5,500,000, of which \$2,500,000 are for water works improvements and \$3,000,000 for trunk sewers, were authorized at a popular election in St. Paul, Minn., on July 16. At the same time a charter amendment was approved that will for the immediate present increase by \$550,000 a year the total amount that may be appropriated by the city for certain purposes. This amendment provides that at least \$400,000 of the amount shall be used to pay (1) the city's portion of paving intersections and (2) the cost of paving that portion of streets that are over 24 ft. wide and (3) to apply on the cost of trunk or main sewers.

The chief purpose for which the water-works bonds will be used is for an 8-ft. reinforced-concrete conduit to parallel the present brick conduit, built in 1885 from Vadnais Lake to the city. The estimated cost of the new conduit is \$900,000. Other conduits and open channels connecting the Vadnais Lake system are estimated to cost \$150,000; new feeder mains to new districts in the city, \$600,000, and new distribution mains and meters, \$170,000 a year for a period of five years.

The \$3,000,000 trunk sewer bonds will provide for what is known as the belt line in the northeast part of the city at an estimated cost of \$1,200,000; Trout Brook extension, \$700,000; the Maryland-Como system, \$400,000, besides seven other projects ranging in cost from \$30,000 to \$200,000.

U. S. Engineers Order Survey in Los Angeles

Washington Correspondence

A survey of the port development at Los Angeles has been ordered by the Board of Engineers for Rivers and Harbors. This survey, however, is not to include the proposed extension of the breakwater so as to shelter Terminal Island. The hope is expressed at the Corps of Engineers that this survey can be co-ordinated closely with that of the municipality. If that can be arranged, much duplication and unnecessary expense can be avoided, it is believed.

The proposal to establish terminal facilities on Terminal Island does not meet with the approval of many of the Government's engineers who have looked over the project. They see no reason for expending \$8,000,000 to extend the breakwater especially in view of the experience indicating the inadequacy of breakwater protection against the surges which characterize the Pacific.

In addition to the drawbacks of the physical formation of the Island, it is pointed out that inside terminals would be justified if there were no other argument in their favor than the better accessibility from the land side.

Architects' Bridge Design Again Under Discussion

Three Allegheny River Bridges In Pittsburgh To Be Rebuilt—Engineers Design Declared Unworthy

Controversy over whether important bridges should be designed by architects has again broken out in Pittsburgh, where discussion of the same kind developed four years ago. At that time the county commissioners retained two architectural firms for the design of two of the new Allegheny River bridges, that at 40th St. and that at 16th St., the architects to have full direction of both design and construction. Protests by the American Institute of Consulting Engineers, the Board of Direction of the American Society of Civil Engineers, and the Engineers Society of Western Pennsylvania against this delegation of engineering work to persons not trained in the problems and art involved were of no effect. The present controversy involves the 6th, 7th, and 9th St. bridges, which must be rebuilt under orders of the War Department for more clearance and channel width.

WORK DELAYED

Work on these three bridges has been delayed by the county officials for a number of years, and appeal made to the War Department to receive its order for the raising of bridges over the Allegheny River issued seven years ago. However, early this year the department reaffirmed its position that the bridges must be raised, and the county is now preparing to proceed with the work.

Preliminary plans for the 7th St. bridge were prepared last spring by V. R. Covell, county engineer, and were approved as to channel location and clearance height by the War Department. The design was then submitted by the county to the Pittsburgh Art Commission, whose approval is required for all city structures exceeding \$25,000 in cost but which has no authority over county construction; this commission declared the county design to be "inadequate and unworthy." Later the county commissioners requested the local chapter of the American Institute of Architects to recommend a number of architectural firms for the artistic development of the three bridges.

Prior to this a joint conference committee of the chapter and the Engineers Society of Western Pennsylvania had considered the question of engineering and architectural work in bridge design, and under date of May 22 passed a resolution recommending that the county engineer be in direction of the design and construction of the bridges, that engineering and architectural consultants of experience be retained to advise him, and that the architect be recognized as an important

(Continued on p. 157)

Design of Bear Mt. Bridge Attacked as Ugly

Contributing Editor of the Outlook
Characterizes Structure as Shown
by Artist as "Tin Trumpetry"

An attack on the design of the Bear Mountain suspension bridge across the Hudson River, now under construction, was published by Lawrence S. Abbott, contributing editor of *The Outlook*, in the July 18 issue of that magazine. The article says that because a beautiful bridge would draw sight-seeing tourists to New York and so "promote the money-making power" of the city, the Bear Mountain bridge design should be deplored; that the men who conceived the structure are apparently not men of architectural training; and that the bridge, judged by an artist's aerial perspective of the design (reproduced herewith), "looks in its wonderful setting of mountains and river like a piece of tin trumpetry." It charges that many good judges are united in saying that the piers "look like poles carrying high-tension electrical power" and should be of stone. And, after admitting that the author is not competent to say what kind of bridge should be built at the site, it affirms that the design shown is "hopelessly incompetent." Finally, the article rumors that members of the Palisades Park Commission are interested in the bridge as stockholders, that they are thus acting as judges in a matter in which they have a pecuniary interest, and that "they are permitting an impression to get abroad that they are not insisting on a clean-cut distinction between questions of private profit and public trust."

The Palisades Park Commission, an interstate body of New York and New Jersey in charge of the management of Bear Mountain Park, a forest reservation along the west side of the Hudson, which the western end of the bridge touches, authorized the bridge

company to build its approach, and in this connection approved the design after certain minor changes were made.

J. D. White, chairman of the Palisades Park Commission, in a statement replying to the article, says that upon receiving the original design the commissioners criticized the piers and engaged the best architectural advice obtainable, with the result that the design was changed. He also says that the legislative charter specified steel towers, and that the commission was bound by this requirement; and he cites the approval of the plans by the state engineer, the War Department, by William H. Burr, consulting engineer, and experts of the commission.

Speaking for the company which is building the bridge, E. Roland Harriman, president, says:

"The type of design was accepted after expert study of its soundness and adequacy and the consideration of other types. Eminent engineering and architectural advice was sought, and while it was realized that massive stone towers and corresponding architectural treatment would undoubtedly add to the attractiveness of the bridge, it was found that adequate structures of this nature were impossible because of the physical limitations of the site and would involve an additional cost that was prohibitive. The company was, therefore, confronted with the alternative of providing a well designed and adequate bridge which will be of the greatest benefit to the public and the state or the abandonment of the project, of which it chose the former. It is felt by those responsible for the affairs of the bridge company that they are willing to rest their case on the merits of the design when the project is complete."

The bridge has a span of 1,632 ft. between towers, and side spans of 210 ft. each. The cable sag is 200 ft. and the camber of the roadway in the main span about 15 ft. It was designed by Howard C. Baird.

A.A.E. to Ask Congress Investi- gate Dismissal of A. P. Davis

A congressional investigation of the dismissal of Arthur P. Davis as director of the U. S. Reclamation Service will be asked for by officials of the American Association of Engineers, the matter to be followed up by the committee on political policies. The Civil Service Reform League has been urged by A.A.E. to look into the circumstances of the dismissal.

"Information from several sources all point to this course as the wise one," said Webster L. Benham, president. "We admit at the outset that in the selection of an executive, the person directly responsible for the work is entitled to exercise his judgment in appointing his subordinates. While this is the essence of executive control, we view with grave concern the dismissal without notice of an admittedly capable engineer who has been in administrative charge of an important government service for many years. We are particularly concerned in that such is purported to have been accompanied by threats intended to intimidate Mr. Davis into giving out publicly a statement that the resignation was initiated by himself."

New York-Duluth All-Water Service to Be Opened

A nine day all-water service between New York and Duluth without transshipment, starting in August, is announced by the Minnesota-Atlantic Transit Co. The route will be by way of the Hudson River and the Barge Canal to Oswego on Lake Ontario, thence by way of the Great Lakes and the Welland Canal to Duluth. The motor barges will be 285 ft. long by 42 ft. wide, and 19 ft. deep, with a carrying capacity of 2,000 tons. They will be propelled by Diesel engines and will operate under their own power.

ARCHITECT'S AERIAL PERSPECTIVE OF THE BEAR MOUNTAIN SUSPENSION BRIDGE

Bridge Design of Architects Again Under Discussion

(Concluded from p. 155)

factor. The resolution also advised against professional competition for designs. On July 10 the architects' chapter submitted the names of thirteen architects for the design and supervision of bridge construction and at the same time disavowed the committee resolution as not representing architectural opinion and as having been unauthorized.

On the architectural attitude the following statement of E. B. Lee, president of the chapter may be quoted, "No city in the world's history has ever had such an opportunity to design and erect in one group three great bridges under a comprehensive plan, which thus gives their creators so rich a chance to consider the whole picture as it shall be presented to the eye up the river, down the river, and from either shore." John W. Beatty, director emeritus of the department of fine arts, Carnegie Institute, who has taken a prominent part in the movement to place architects in charge of the bridge design, said in regard to the request of the county commissioners for names of architects, "This simply means that able men will finally be chosen to create the designs for these bridges and that they will be architecturally important and beautiful. This is as it should be. The day has gone by for the erection of bridges without regard to grace and beauty of line. Pittsburgh will therefore take a foremost place among American cities in this respect and I predict that it will in time become known as the City of Beautiful Bridges."

ENGINEERS PROTEST

Resolutions of protest against the delegation of the bridge design to architects have been passed by the Engineers' Society of Western Pennsylvania and by the Board of Direction of the American Society of Civil Engineers. Protest was also made by the Pittsburgh chapter of the American Association of Engineers, pointing out that safe and proper construction is the primary essential in bridge design and that architectural appearance is only of secondary importance. The resolution of the Board of Direction of the American Society of Civil Engineers is as follows:

Whereas, it has been brought to the attention of the Board of Direction of the American Society of Civil Engineers that the Commissioners of the County of Allegheny, Pennsylvania, have under consideration the employment of architects for preparing plans and specifications and for supervising the construction of several important bridges in the city of Pittsburgh and

Whereas, these bridges are primarily engineering works demanding safety and economy and involving principles of design, construction and maintenance which come indisputably within the province of engineers and

Whereas, it is detrimental to the public interest to subordinate safety utility adequacy for future traffic and cost of these structures to their appearance, although it is recognized that the embellishment and aesthetic features of bridges may properly be entrusted to those especially skilled in architecture

Therefore be it resolved, that the responsibility for the design

Santa Fe to Spend \$60,000,000

The need for additional railroad facilities is noted in the annual report of the Atchison, Topeka & Santa Fe Ry., which states that: "One outstanding feature of the year's railroad operations is the clear demonstration of the country's imperative need for greatly increased transportation facilities, a need which has been realized and persistently urged by the railroads since the termination of federal control." At the beginning of 1922 the company undertook as large a program of improvements as seemed possible and carried it through; but only a beginning was made of providing for the traffic demands of its territory.

For the year 1923 contracts were let for 7,150 freight cars and 59 new locomotives; this equipment with passenger cars on order and improvements to existing equipment, will cost upward of \$24,000,000. The second-track work undertaken and authorized since the beginning of 1922 involves an expenditure of over \$15,000,000. Preliminary work is under way for a new double-track bridge over the Mississippi River, on the Chicago-Kansas City line, to cost \$4,000,000. Enlargement of shops, terminals and sidings will be pushed and it is probable that cash expenditures during the year for all improvements and equipment will amount to at least \$60,000,000. "The improvements have been practically confined to what will increase handling traffic, other improvements, even though desirable, being deferred, because the present program is all that the company can efficiently handle this year."

Southern Pacific Co. Surveys New Line in Oregon

Surveys for a new railway line to connect California and Oregon are now being made by the Southern Pacific R.R. Co. The new line which is in the old Central Pacific territory will extend from Kirk, a point southeast of the Cascade Mountains, over the mountain to Oak Ridge, a distance of about 118 miles. Construction was started on this line a few years ago working from both ends but it was stopped by the central & Southern Pacific litigation and will not be taken up again until this litigation is settled.

N. Y. Aerial Survey Proposed

Aerial photographic maps of New York City, covering the area within the legal limits of the city and made on scales of 600 ft. and 2,000 ft. to the inch, are soon to be made by the Fairchild Aerial Camera Corp. It is expected that the photography will be completed by November 1 and that the maps made therefrom will be finished about April 1, 1924. The proposed aerial survey is strictly a city enterprise and title to all photographic negatives, as well as reproduction rights, will be vested in the city under the terms of the contract.

and supervision of construction of such bridges should be entrusted only to qualified civil engineers and that a copy of this resolution be transmitted to the Commissioners of the County of Allegheny through the Secretary of the Pittsburgh Section of the American Society of Civil Engineers.

Hirst-Potts Charges Are Modified at Hearing

"Revenge" Only Motive Now Charged Against Potts—Stock Conferences Before Trenton Plans Filled

Modification by E. Jerome Hirst of the Direct-Oxidation Disposal Corp., of Philadelphia, of the charges made by him to Governor Silzer against Clyde Potts, an engineer-member of the New Jersey State Board of Health, in connection with the Trenton sewage-works plans, was the chief feature of the hearing at Trenton July 24. The hearing was held by Dr. J. C. Price, director of the New Jersey Department of Health, at Gov. Silzer's request.

In Mr. Hirst's charges dated Feb. 19, 1923, he alleged that failure of the Board to act on Trenton's application for a sewage-works permit filed Dec. 15, 1922, "was attributable unequivocally to one member of the State Department of Health, Clyde Potts, a consulting engineer of New York and Mayor of Morristown, N. J." In his charges Mr. Hirst said no other motive for Mr. Potts' opposition to the Trenton plans was apparent except that Mr. Potts "sought and was denied donation of a large stock interest in the patented process involved" in the Trenton plans. Mr. Potts sent a letter to Governor Silzer denying the charges, both against himself and as against the other members of the board as having been influenced by him. (See *Engineering News-Record*, March 8, 1923, p. 462; March 15, p. 507; Apr. 5, p. 635.)

At the hearing on July 24 Mr. Hirst voluntarily stated that Mr. Potts had not improperly sought an interest in the Direct-Oxidation Process, while on cross-examination by Mr. Potts' attorney Mr. Hirst made it plain that the stock incident occurred in 1918-1919.

Mr. Hirst brought out nothing at the hearing that was definite as to negotiations with Mr. Potts as to a stock interest in the Direct-Oxidation Process, beyond the statement that a citizen of New Jersey suggested to a man in Reading, Pa., that it would be advisable to engage Mr. Potts' interest in the process; and that Mr. Potts attended several conferences on the subject in 1918-1919, at which various witnesses named by Mr. Hirst were present, and at which Mr. Potts was favorable to the process and alleged that he could help get the process adopted in the Middle West. The Direct-Oxidation people, Mr. Hirst stated, decided against giving Mr. Potts an interest because they finally concluded that to have a consulting engineer thus interested would be bad policy.

Mr. Hirst also stated that his decision to file charges against Mr. Potts was reached on hearing indirectly that Mr. Potts was opposed to the approval of the Trenton plans, after having expressed himself favorably to the process during the negotiations. Mr. Hirst could see neither then nor at the time of the hearing any reason for Mr. Potts' approval except "revenge" and "instinctive opposition."

Mr. Hirst's general statements as to conferences with Mr. Potts about giving the latter an interest in the Direct-Oxidation Process were confirmed by F. D. Chandler, of the banking firm of Chandler Bros., Philadelphia.

Mr. Potts, who was present at the hearing, replied through his counsel that in view of the record it seemed useless for him to make a statement.

Random Lines

"How Firm a Foundation"

Sir—I have noted with interest recent attention paid the ever-widening scope of the engineering profession. I propose a candidate for the concrete moustache-cup. You will find him on the outside back cover of that estimable magazine *The Christian Century*, in an advertisement by that equally estimable publisher, The Century Co. He is the author of "Hymns for the Living Age." But let me quote the advertisement:

"When you plan a church edifice you consult an architect; when you want an organ you go to an organ builder. The hymn-book is just as important. Consult a man who is giving his life to the development of congregational singing. H. AUGUSTINE SMITH, the HYMN-BOOK ENGINEER, has done more for church music than any man of his generation."

K. H. B.

Sir—*Out our way there is a sign "Horticultural Engineer" in large letters across the window front of a place of business on the main street. A little further observation indicates that the chief activity of the proprietor lies in promoting the sale of certain lands, said to be suitable for apple production.*

J. J.

From the Bottom Up?

"RIVET YOUR INVESTMENT TO BEDROCK," says the New York Title & Mortgage Co. (Capital funds over \$8,000,000) in an advertisement headed by this sketch. Here are possibilities of a new form of riveting technique. In

riveting bedrock we can visualize the man who operates the compressed air gun but we can't figure out how the "holder-on" functions.

* * *

They All Look Good When They're Far Away

In America a time-table is not a thing to miss trains by. When it says a train will leave such and such a place such and such a time it does; and, more important still, it sees that it gets there when the time-table says it should. Portion of a coupon ticket issued on one of the American railways was circulated on a Sydney suburban train one morning recently—the train was 55 minutes late—and every passenger read it twice before he'd believe his eyes. It says that if the train arrives at its destination 55 minutes late, the fare—full fare, that is—is to be refunded. Of course, it wasn't a fair thing to circulate in a Sydney suburban business train, running almost an hour late—From the Sydney, Australia, Sun.

Committee to Report California's Highway Needs

The Governor of California has signed a bill passed by the recent session of the state's legislature authorizing the appointment of a committee of nine to enter upon a detailed and comprehensive study of the road problem of the state.

The committee, which is to serve without pay, is to "propose a complete system of state roads, study types of construction and materials to be used, recommend the inclusion of additional mileage, the exclusion of certain legislative roads now included in the system, and the time to be occupied in the completion of the system." This report is to be made to the legislature two years hence and is to include some plan for financing the necessary work. The engineering department of the commission estimates that to complete the 6,500 miles of highway now included in the system will require at least \$200,000,000.

An announcement issued by the Highway Commission in commenting on this states: "To issue bonds for so vast a sum would seem to be bad financing, so some other mode of raising funds for new construction would seem advisable. It might come from a gasoline, weight or tire tax made just sufficiently large to carry construction over a period of years. There is also a widespread and growing sentiment in the state in favor of an oil production tax of a few cents a barrel or small percentage of selling cost."

The bill provides that the new committee shall be composed of the state highway engineer, one member of the state highway commission, one member of the state board of control, one member each from the state senate and assembly and four from the state at large to be named by the governor.

Steel Canopy Over Broad Street Station Being Removed

Work of removing the steel canopy that covered the fire-wrecked Broad Street station of the Pennsylvania R.R. is progressing rapidly. The wooden understructure has now been completed, and demolition of the steelwork started last week.

The scheme of demolition is by use of a wooden structure erected upon four-wheel car trucks. This wooden structure has a platform at the top from which the steel canopy can be reached. A central section of the wooden falsework reaches to the top of the structure. Two canopies on each side cover the tracks being used for trains, protecting them and at the same time providing space for handling members removed from the structure. The central traveler is capable of reaching any portion of the shed roof. Railroad engineers state that the demolition will require four to six weeks.

A feature of the recent fire on the trainshed is the effect of the fire upon the paint. In several places on the north wall of the shed, the outer coat of black paint has been blistered and has chipped off completely, but the priming coat of red lead paint is bright and in good condition. Most of the spots where such effect is noted are near the floor level where the heat was less intense, but a few spots are about half way up the structure.

Jobs Open for Reserve Officers

The Corps of Engineers will employ reserve officers as civilians, according to an announcement made by the Chief of Engineers on an important survey being made of the Tennessee River, under direction of the District Engineer in charge of river and harbor work at Chattanooga. The work will include the preparation of maps by aerial photography surveying and the collection and interpretation of stream-flow data. Experience in hydro-electric power and flood-prevention work will be an advantage. Salary will be from \$200 to \$325 per month and the period of employment will be one or two years. Positions are also announced by the District Engineer at Chattanooga for three junior engineers to assist in making computations, plans and estimates of navigation and power plant structures, and six junior engineers to take charge of survey parties.

18-Ft. Channel for Merrimack Is Subject of Controversy

Washington Correspondence

That the Board of Engineers for Rivers and Harbors does not regard an 18-ft. channel in the Merrimack River as an entirely practicable improvement could be judged from the attitude of members of the Board at the recent hearing in which the advisability of such a channel was urged by numerous witnesses. They argued that this channel would provide cheap transportation to the several populous mill towns along the Merrimack. The principal need for the channel, it was contended, is to bring in coal.

Representatives of the mills and other industries, however, testified that they are opposed to the project. It is their opinion that it would not justify the \$12,000,000 or more which it would cost, at least half of which would have to be raised by the local interests. A depth of 18 ft., they pointed out, would be inadequate for the ships engaged in the coastwise coal trade.

Civil Service Examination UNITED STATES

For the U. S. Civil Service examinations listed below apply to the United States Civil Service Commission, Washington, D. C., or to any local office of the Civil Service Commission.

Valuation Engineer, and Associate Valuation Engineer—Vacancies in the Technical Staff of the Income Tax Unit of the Bureau of Internal Revenue, Treasury Department: valuation engineer in oil and gas, mining, timber, salary \$3,600 to \$4,800 a year; associate valuation engineer, salary \$3,000 to \$3,600. Applications must be filed with the Civil Service Commission, Washington, D. C., on or before August 31, 1923.

Junior Engineer, U. S. Geological Survey—Vacancy in the Water Resources branch of the Geological Survey, at entrance salary of \$1,620 a year plus increase of \$20 a month granted by Congress; work to consist of field investigations in any part of the United States, and the writing and review of resulting reports. Applications must be filed with the Civil Service Commission not later than Sept. 25, 1923.

Personal Notes

W. E. ANDERSON, engineer of Cameron County Water Improvement District 2, has resigned and accepted a position as manager of Cameron County Water Improvement District 3 at La Feria, Texas. During his three years' service with District 2, Mr. Anderson has also had charge of the street paving of San Benito, Texas, and has served as consulting engineer on the construction of the pumping plant and distribution system for Nueces County Water Improvement District 3 at Robstown, Texas, besides other consulting work in the valley.

G. F. SCHLESINGER, formerly chief deputy of construction in the Ohio department of highways, has been named state highway engineer of Ohio. Mr. Schlesinger was for several years assistant professor of civil engineering at Ohio State University and had served five years with the Rock Island Lines as assistant engineer on the St. Louis division.

DR. MATTHIAS NICOLL, JR., deputy commissioner of health of New York State, has been appointed commissioner to succeed the late Dr. Hermann M. Biggs. Dr. Nicoll was secretary of the department and director of public health education from 1914 to 1919 and has been deputy commissioner since the latter date. Before going to Albany he had been associated for many years with Dr. Biggs and with Dr. William H. Park in public health and laboratory work in the New York City Department of Health.

LEWIS D. ASMUS, of the U. S. Bureau of Public Roads, District 6, located in the Austin, Texas, sub-office, has been transferred to Baton Rouge, La., as assistant to M. J. Cramer, senior highway engineer, in charge of the State of Louisiana for the Bureau.

COLONEL FREDERICK MEARS, chairman and chief engineer of the Alaskan Railway Commission, has been appointed chief engineer of the Union Depot Co., St. Paul, Minn., to succeed WILLIAM C. ARMSTRONG, recently deceased.

WILLIAM E. WHITE, civil engineer, formerly in the Iowa State Highway Department's testing laboratories at Ames, has accepted a position with the George T. Wilhelm Co., construction engineers of Cedar Rapids, Iowa, for work on a 19-mile concrete road contract in Dyer County, Tenn.

A. S. HOLWAY, superintendent and chief engineer of the water-works of Oklahoma City, Okla., has resigned and his resignation has been accepted by the city commissioners. Mr. Holway will continue for a short time as supervisor of construction on the new filtration plant which is now nearing completion, after which he will join his brother in Tulsa in engineering work.

MARSHALL W. MARTIN, traffic commissioner of Arkansas, is now traffic manager for the George T. Wilhelm Co., construction engineers, Cedar Rapids, Iowa, and is located at Helena, Ark. He is in charge of materials on their contracts in southern territory.

JOHN L. LEHMAN, an engineer of Denver, has been made superintendent of the Trinidad, Colo., water-works. He

succeeds Walter R. Lewis, who recently resigned after sixteen years' service in the department.

JEPHTHA A. WADE, who has been engaged for the last two years on the design and construction of a pumping station, at Harrisburg, Pa., where he has been in charge representing James H. Fuertes, New York, has completed this work and is now with Viele, Blackwell & Buck, consulting engineers, New York.

RALPH H. GREENWOOD, who for the past three years has been conducting a private practice at Hamburg, Iowa, has taken a position as locating engineer with the state highway commission of South Dakota at Pierre.

position with A. Bentley & Sons, contractors of Ohio. He will be stationed at Jacksonville, Fla., beginning August 1.

TOM J. ALLEN, who served during the World War as captain of engineers, has been elected city manager of Coronado, Calif., succeeding G. FRANK HYATT, resigned. Following the war Mr. Allen entered the service of the Erie R.R. as assistant division engineer at Youngstown, Ohio, and more recently has been connected with the engineering department of the Santa Fe R.R.

HADLEY BALDWIN has been promoted from assistant chief engineer to assistant to the general manager of the Cleveland, Cincinnati, Chicago & St. Louis R.R., with offices at Cincinnati, Ohio.

J. A. LENECEK has resigned from the engineering and construction department of the Erie R.R. at New York and accepted the position of chief engineer of the Quito-Esmeraldas R.R. in Ecuador. Mr. Lenecek will be in complete charge of locating, design and construction of this lengthy connection of the Ecuadorian capital with the sea coast.

EUGENE H. PAULUS has resigned as architect and construction superintendent of Federal Home Builders Corp. and is entering business under the firm name of E. H. Paulus Co., 4955 Northland Place, St. Louis, Mo.

M. H. MERRILL & Co. of Boston have opened an office in Dallas, Texas, at 608 Interurban Bldg. with Charles C. Allen as southwestern manager. This firm specializes in the design and construction of textile mills.

JOHN R. NICHOLS has opened an office at 161 Devonshire St., Boston, Mass., as consultant and designer in civil and structural engineering. Mr. Nichols graduated from Harvard in 1906, was for three years designer with contractors specializing in reinforced-concrete construction, four years instructor in mechanical and civil engineering at Harvard, and ten years with Monks & Johnson, architects, Boston, the last five years as their chief engineer.

LORENZO HAMILTON, architect and engineer of Meriden, Conn., has recently moved to new offices in the Dondero Building, that city.

SHEVLIN ENGINEERING Co., of New York City, power plant engineers, has recently established a branch office at 821 Chapel St., New Haven, Conn., with W. V. Pietsch as manager.

WYTHE M. PEYTON, Asheville, N. C., district engineer of the 9th district of the North Carolina state highway commission, has resigned and has opened an office in Asheville as a consulting engineer. JOHN C. WALKER, construction engineer of the highway commission, has been appointed to succeed Mr. Peyton.

J. C. NAGLE of the firm of Nagle, Witt & Rollins, consulting engineers, Dallas, and T. A. THOMPSON, chief engineer of the Wichita Falls Water Improvement District, have been selected as consulting engineers on the location of the proposed new Dallas reservoir for which \$5,000,000 in bonds has been voted. Mr. Nagle is a member of the

Engineering Societies

Calendar

Annual Meetings

NEW ENGLAND WATER WORKS ASSOCIATION, Boston, Mass.; Annual Convention, Burlington, Vt., Sept. 18-21, 1923.

AMERICAN PUBLIC HEALTH ASSOCIATION, New York; Annual Meeting, Boston, Oct. 8-11.

AMERICAN SOCIETY OF CIVIL ENGINEERS, New York; Fall Meeting, Richmond, Va., Oct. 15-17.

AMERICAN SOCIETY FOR MUNICIPAL IMPROVEMENTS, St. Petersburg, Fla.; Annual Convention, Atlanta, Ga.; Nov. 12 to 16.

KALTENBACH BROS. have opened offices at 201 Board of Trade Building, Wheeling, W. Va., to engage in civil and architectural engineering work.

WEBSTER P. BUSHNELL, city engineer of Quincy, Ill., in 1912 and 1913 and civil engineer connected with various levee districts, specializing in reclamation of swamp and overflowed lands in Illinois and Missouri, has been again appointed city engineer of Quincy, Ill.

E. B. HILLMAN, formerly engineer and contractor, has been appointed a member of the board of local improvements at Quincy, Ill.

WILLIAM F. COCKE, state highway engineer of Florida, resigned July 10. No reasons have been announced for the resignation.

G. FRANK HYATT, formerly city engineer of East San Diego, Calif., and for the past three and a half years city manager of Coronado, Calif., has resigned to accept a position with the Bent Concrete Pipe Co. of Los Angeles.

HARRY J. KIRK, Defiance, Ohio, has been appointed chief engineer of maintenance in the Ohio Department of Highways and Public Works. Louis A. Boulay, director of the department, has also appointed the following division engineers: GEORGE E. CARR, Marietta, Ohio, District 10; MARTIN I. HENAHAN, Toledo, District 2; F. A. DAUM, Defiance, District 1; and FRED E. SWINEFORD, Akron, District 4.

FRANK W. SALFENGERE, civil engineer, has resigned his position as superintendent of construction at Fort Benning, Ga., to accept an engineering

firm who are district engineers for Dallas County on highway construction. He has been at various times dean of engineering at Texas A. & M. College, on the State Board of Water Engineers, and a major of engineers in the Officers Reserve Corps. Mr. Thompson is a hydraulic engineer of long practice in the southwest; he was both a designer and construction engineer of the Wichita Falls project.

Obituary

WILLIAM HOLABIRD, of Holabird & Roche, architects, Chicago, died July 19 at the age of 69 years. Following two years in West Point he spent several years in the office of W. L. B. Jenney before organizing the present firm of Holabird & Roche. He was one of the first to use steel-skeleton building construction, and is sometimes credited with originating the type. His first application of it was in the Tacoma building, at Madison and LaSalle Sts., Chicago. Subsequently his firm was the architect for the other three buildings on the same corner, LaSalle Hotel, Otis building, and Lumber Exchange. Mr. Holabird was one of the first to use sub-basement space, first in the Tribune building. His firm's latest structure in Chicago is the Chicago Temple building.

GEORGE WHITNEY BATES, city engineer, Lincoln, Neb., died July 11. Born 44 years ago in Hartford, Conn., Mr. Bates was educated at the University of Nebraska. From 1901 to 1907 he was a United States land surveyor in South Dakota and became deputy state engineer of Nebraska in 1905. Four years later he entered city service in the position retained until his death.

SIR JOHN STRATHEARN HENDRIE, president of the Hamilton Bridge Works Co., Hamilton, Ont., and former lieutenant-governor of Ontario, died July 17 at Johns Hopkins Hospital, Baltimore, aged 65 years.

THEODORE ISSON, of Chicago, structural engineer in charge of construction on a Fort Dodge, Des Moines & Southern Ry. bridge across the Des Moines River at Rivera, near Boone, Iowa, was electrocuted when the derrick on which he was working came in contact with a trolley wire. The heavy current had been ordered shut off, but before the disconnecting switch was turned the contact between derrick boom and trolley wire had been made. The accident happened July 12.

MAJOR HENRY H. WADSWORTH, consulting engineer of San Francisco, died in that city on July 11 after an illness of several months. Major Wadsworth graduated from Sheffield Scientific school, Yale, in 1886. For fourteen years he was engineer for the California Debris Commission; during the war he held the rank of Major, Engineer Corps, U.S.A.; and last year he was chairman of a committee selected by the Oakland Chamber of Commerce to investigate the water supply of the East Bay cities and make recommendations for necessary developments. At the time of his death he was vice-president of the San Francisco Section Am. Soc. C. E.

From the Manufacturer's Point of View

A Point of Contact
Between Maker and User of
Construction Equipment and Materials

Canvass Opinion on Need of 21-S Concrete Mixers

Joint Committee on Construction Equipment
Queries Contractors as Part
of Standardization Program

Members of the Associated General Contractors of America are being asked for their opinion as to the advisability of manufacturing side-loading building mixers with a capacity of 21 cu.ft. Ballots are being sent out by the Joint Committee on Construction Equipment, which met in Chicago June 27-29, as reported in *Engineering News-Record* of July 5, p. 36, and July 19, p. 120. At that meeting there was a difference of opinion among concrete mixer manufacturers as to the need for the 21-S mixer. Certain companies believed that two sizes larger than the 7-S, namely the 14-S and the 28-S, were capable of serving the industry satisfactorily; others felt that the 21-S size should be included. It was agreed, therefore, to ascertain the desires of contractors.

In the Joint Committee's report it is stated that if the 21-S size is desired its capacity shall be a four-sack batch of 1:2:4 mix and a three-sack batch of 1:3:6 mix, based upon 40 per cent of voids in sand and stone and a maximum of $1\frac{1}{2}$ gal. of water per cubic foot of mixed concrete.

ARGUMENTS, PRO AND CON

The size under discussion is that commonly designated as a $\frac{3}{4}$ -yd. mixer. From the construction viewpoint the real issue is whether the job economies actually necessitate a mixer of this size.

The points mentioned in favor of the 21-S mixer were as follows:

(1) The weight and capacity of the 21-S fit in economically with many jobs where the larger machine would be cumbersome and over-sized.

(2) Some construction companies are already standardized on a $\frac{3}{4}$ -yd. machine and would not like to change.

(3) The $\frac{3}{4}$ -yd. machines can be more conveniently moved from one city job to another than the 1-yd. machines.

(4) The job economies create a need for both the $\frac{3}{4}$ and the 1-yd. mixer.

In opposition to the 21-S size it was pointed out: (1) Certain mixtures of concrete for full-sack batches will overrun the capacity of a $\frac{3}{4}$ -yd. machine and necessitate using either the 28-S at a slightly reduced capacity or the $\frac{3}{4}$ -yd. machine at the next lower even-sack batch.

(2) The drum of the 28-S building mixer is used on the 21-E paver and elimination of the $\frac{3}{4}$ -yd. machine will permit greater production on a single size, reducing the number of parts and the production costs.

(3) Sales during the past year indicate that the 28-S is growing in favor.

(4) Concrete towers are being standardized on 1-yd. capacities.

(5) The 28-S can be operated economically at less than full capacity and covers a wider range of jobs than the 21-S.

To Reduce Wire Fence Styles

Elimination of 87½ per cent of the styles of woven-wire field and poultry fences was recommended at a conference July 12 between manufacturers representing 85 per cent of the fence manufacturing capacity of the United States and W. A. Durgin, chief of the Commerce Department's Division of Simplified Practice. The recommendations include that no rolls of poultry fence be manufactured except 10 and 20 rod rolls and that no rolls of field fence be manufactured except 10, 20, and 40 rod rolls.

A. G. Moore of the Fence Institute and chairman of the committee representing the fence manufacturer, declared that "if the above styles are adopted by the entire fence industry, as recommended, the styles now made by 27 manufacturers will be reduced from 552 styles to 69. Considering all of the different sized packages as previously made there was a total of 2,072, while in the simplified program there are only 138 packages.

Standards for Wheelbarrows Approved by Committee

At a meeting of the Joint Committee on Construction Equipment held in Chicago, June 27-29, wheelbarrow manufacturers representing about 95 per cent of the construction wheelbarrows production of the country presented for approval a report on the standardization of wheelbarrows and a plan for establishing the standards. Their report was approved by the Joint Committee in accordance with the following:

With respect to trays wheelbarrows were grouped into four classes as follows:

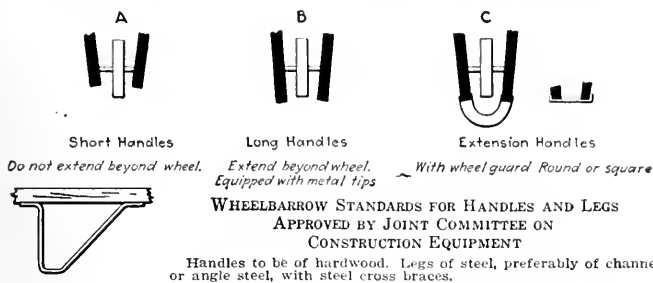

Class	Capacity Cu.ft.	Gage
1	2	18-15
2	2½	16or15
3	3	16
4	3½	16

Classes 1 and 2 have trays of medium capacity intended for dry material wheeling. The capacities are struck level capacity of dry material. For wet material figure one-third less capacity in wheeling position. For heaped dry material capacity add one-third to struck capacity.

Classes 3 and 4 have deep trays intended especially for wheeling wet materials. The capacities rated, however, are level full dry material. Figure one-quarter less of wheeling capacity for wet materials, and add one-third for heaping capacity of dry materials.

Three types of handle were adopted as shown in the accompanying sketch. All handles are to be of hardwood. Wheelbarrow leg construction for A. G. C. A. requirements is of steel, preferably of channel or angle steel, with steel cross-braces.

The final development of the standards is to be officially tied in with the American Engineering Standards Committee, and sponsorship for the development is to be placed with the Associated

General Contractors of America and the American Society of Mechanical Engineers.

Standards are to be designated as A. G. C. standards until such time as the American Engineering Standards Committee authorizes them to be designated as American Standards.

The proposed standards are to become effective upon approval of the Executive Board of the Associated General Contractors and will as soon as possible thereafter be followed in the manufacture of wheelbarrows.

Large Use of Equipment Indicated by Federal-Aid Road Program

For manufacturers of road building equipment and materials the extent of the federal-aid road building program is indicated by the mileages, by states in the accompanying table. Roads which will comprise the federal-aid system of highways have been definitely designated in 34 states according to the U. S. Bureau of Public Roads.

A study of the system in the 34 states now approved shows that nearly every city of over 5,000 population is located upon it and the few which are not will connect with it over improved roads. The indications are that over 90 per cent of the entire population of the United States will live within 10 miles of a federal-aid highway. In a number of states the figure is as high as 98 per cent and in none of the states will it drop below 65 per cent.

In the tabulation of the mileage in the system by states estimates are given for those states whose systems are not yet approved.

MILEAGE OF FEDERAL-AID HIGHWAY SYSTEM

Nine Cities Report Cast-Iron Pipe Mileage

From nine of the large cities of the United States the Cast Iron Pipe Publicity Bureau, Chicago, has secured figures indicating the mileage of cast-iron pipe used in their distribution systems. New York has the largest mileage and Philadelphia shows the earliest use of cast-iron pipe.

City	Total Miles Of Cast Iron Pipe	Date First Cast Iron Pipe Laid
New York.....	3,060.0	1832
Chicago.....	3,027.1	1852
Philadelphia.....	1,749.0	1801
Detroit.....	1,732.0	1838

Construction Machinery Statistics Compared for 1914 and 1919

Based on the fourteenth census (1919) of the United States, the Department of Commerce has compiled statistics on the number and value of the country's industries. Those relating to machinery employed in the field of engineering and construction for the years 1914 and 1919 are presented below.

7-MACHINERY IN CONSTRUCTION FIELD

Class	Census Year	Number of Establishments	Value of Products
Air compressors.....	1919	44	\$18,650,074
	1914	84	5,158,127
Blowers and fans.....	1919	69	12,121,740
Brick and clay machinery.....	1919	49	3,187,563
	1914	89	2,478,861
Concrete mixers.....	1919	62	10,450,334
	1914	44	2,956,638
Cranes			
Electric.....	1919	36	27,324,864
	1914	84	5,158,127
Hydraulic and steam.....	1914	16	13,972,133
All other.....	1919	59	11,237,025
	1914	26	4,194,457
Dredging machinery.....	1919	9	1,824,025
Elevators and elevator machinery.....	1919	94	29,607,380
Electric.....	1919	157	40,579,919
All other.....	1914	213	17,228,101
Excavating machinery.....	1919	38	7,284,333
	1914	21	2,968,965
Meters, gas and water.....	1919	111	27,764,884
	1914	40	11,638,074
Mining machinery.....	1919	133	51,243,489
	1914	153	13,253,634
Pumps and pumping machinery.....	1919	228	66,456,444
	1914	298	27,456,916
Road making machines.....	1919	38	15,777,652
	1914	31	3,547,272
Steam shovels.....	1919	8	12,433,763
	1914	1	
Well-drilling machinery, other than oil well.....	1919	30	2,566,665

Patent Office Rules on Trade Name

Trade marks involving an identical name may be used on products sufficiently unlike in character to avoid confusion in the user's mind. This, in effect, is the decision of the U. S. Patent Office in a case involving the use of the word "Eversharp" by the American Safety Razor Corp., Brooklyn, N. Y., as a trade mark for safety razors and blades, notwithstanding the prior use of the same trade mark by the Eversharp Pencil Co., Chicago. According to the Patent Office ruling the goods of the two companies are not sufficiently alike to cause confusion in trade by reason of the simultaneous

Winter Discounts on Materials Sought by Contractors

Following the convention in Los Angeles last spring, the Associated General Contractors of America, through its committee of methods, is seeking from material manufacturers winter discounts on their products in order to equalize sales throughout the year, insure early deliveries and reduce shop costs. It is pointed out by the contractors that early delivery of materials on the construction site means an early start in construction work each year and thus tends to lengthen the construction season. This result, coupled with an increased use of construction machinery, it is hoped, will offset the shortage of labor.

A. P. Greenfelder, chairman of the Committee of Methods of the A.G.C., has prepared a memorandum headed "Winter Discounts—Fourteen Points" reproduced herewith.

Winter Discounts

Reduce construction costs.
 Induce twelve months' sales.
 No pyramiding of peak prices.
 Lengthen construction season and insure early spring field work.
 Reduce shop costs.
 Discourage seasonal unemployment.
 Intelligently reward early buyers.
 Make savings to users and manufacturers.
 Cause continuity of manufacture.
 Reduce overhead costs.
 Create uniformity in production.
 Cut transportation delays.
 Take account of steady labor.
 Standardize factory practice.

It is suggested by the contractors that manufacturers offer a winter discount on contracts awarded in December, January and February, and only on such shipments on these contracts as are made within these months.

Brick Men to Meet in Los Angeles

The Common Brick Manufacturers' Association of America, Cleveland, will hold its next annual convention during the week of Feb. 11, 1924, in Los Angeles, according to a decision reached at a recent meeting of the board of directors.

The increased activity in the brick producing field on the Pacific Coast during recent years was a strong factor in deciding to hold the next convention in California.

use of the mark on their goods. It was held, also, that the likelihood of the Eversharp Pencil Co. expanding its business to include razors was not such as to warrant a claim of interference with its business expansion and also that the mark was not merely the essential feature of the corporate name of that company.

Business Notes.

GUY H. HALL, formerly director of the National Institute of Progressive Farming has been appointed manager of the division of public relations and sales promotion, newly created by the Holt Manufacturing Co., Peoria, Ill., and Stockton, Calif., manufacturer of Caterpillar tractors.

FOAMITE-CHILDS CORP., Utica, N. Y., manufacturer of fire-protection equipment and motor street sweepers, has leased a 2½-acre plot near its present plant for the construction of an outdoor experiment station.

M. P. MATTHIAS, export manager of the Foamite-Childs Corp., Utica, N. Y., manufacturer of fire-protection equipment, has sailed for South America on a tour which will include visits to the company's agencies in the Latin American republics.

FRED H. MARSH, formerly with the Pittsburgh-Des Moines Steel Co., Des Moines, Ia., is now with the Paxton & Vierling Iron Works, Omaha, Neb.

J. C. BLOOMFIELD, for a number of years with R. W. Hunt & Co., contractors, of Chicago, has assumed charge of the Chicago office of the Industrial Works, Bay City, Mich., manufacturers of cranes.

STROUD & Co., Omaha, Neb., manufacturers of dump wagons and earth-moving equipment, announce an involuntary petition in bankruptcy filed against them July 11. The court will be asked to appoint a trustee so that the business may be continued. The company states that it is in a position to make prompt shipment of elevating graders, dump wagons, scrapers, road maintainers, plows and drags, and that its present condition is due principally to the cessation of new railroad construction, closing a large outlet for earth-moving machinery. Another contributing factor is said to be the present gradual decline in earth-moving prices in the Missouri Valley, amounting to 20c. per cubic yard this year, as against 25c. in 1922, 40c. in 1921, and 60c. in 1920.

CONVEYORS CORP. OF AMERICA, Chicago, announces the appointment of the Pittsburgh Machine Products Co., Pittsburgh, as district representative. The Pittsburgh organization will handle the sale of American steam jet ash conveyors, airtight doors and cast-iron storage tanks, in western Pennsylvania and the northwestern part of West Virginia.

FORT PITT BRIDGE WORKS, Pittsburgh, announces the appointment of H. B. Spearmaker as assistant to President H. H. Bieckle. For twelve years Mr. Spearmaker served as purchasing agent of the Diamond Alkali Co., Pittsburgh.

Equipment and Materials

Gasoline Hoist with Reversing Elevator Sheave

Portability and independence of outside sources of power are among the advantages claimed by the Clyde Iron Works Sales Co., Duluth, Minn., for its new line of gasoline builders' hoists

with reversing elevator sheaves. The hoist shown in the accompanying illustration is built with either one or two drums and an independent clutch elevator sheave which permits double cage operation, and in addition, leaves the friction drum free for hoisting forms, reinforcing, etc.

One exclusive advantage claimed for this hoist is that while the driving gear of the friction drum is non-reversible, the elevator sheave, by means of two separate clutches, may be reversed at will, independently. Patents covering this feature have been applied for. Motive power is supplied by a four-cylinder gasoline engine and transmitted to the drum through a silent belt chain drive.

Two New Models of Portable Building Mixer

Two new models of Rex mixers have been announced by the Chain Belt Co., Milwaukee, a 2-bag mixer known as the 234-S, and a 1-bag machine, the 237-S. Both are low-charging types and can be equipped with either a hinged platform or charging skip. In its new models the company's aim is to bring to the portable building mixer field the speed and low mixing cost of the larger paver.

In the drum of the new models the mixing blades and buckets have been

arranged to decrease the time required for discharging the batch, no matter what mixing proportions are used. The opposite side discharge control is of

a new design to make the operation of the chute easier. The power charging skip has been constructed so as to reduce the time of charging the drum.

By mounting the countershaft up out of the dirt line and using a vertical engine, the new mixers have been made compact and sturdy. A short wheel-base makes them more readily portable, especially in close quarters. The front axle of the truck is built up of cold-rolled shafting and trussed channels to give it great rigidity. An adjustable malleable jack placed on the charging end of the axle gives the mixer four point suspension while mixing concrete.

The superstructure is of heavy steel angles gusseted in both directions. The main countershaft is mounted on self-aligning bearings high up on the machine, where it is accessible. An asbestos disc type of clutch which has a greater gripping area and is smoother in operation has superseded the old wood-block type of clutch. Self-oiling bushings are provided in the drum rollers which are of malleable iron construction.

The Rex 237-S is equipped with an 8 h.p., two-cylinder vertical, hopper-cooled Le Roi engine having a high-tension magneto, an automobile type carburetor and a throttling governor. On the Rex 234-S a 4 h.p. vertical gasoline engine is used. Rubber-tired disc wheels or built-up wheels are optional equipment. The disc wheels are equipped with phosphor bronze bushings to allow faster traveling over city streets.

Air Spring Seat for Drivers of Trucks or Tractors

To protect the health and insure the comfort of drivers of tractors or trucks an air spring seat has been designed which, according to its manufacturer,

the Seibel Air Spring Co., Inc., San Francisco, eliminates vibration and jolting even over rough ground. The seat, which may readily be attached to a tractor or truck, involves an adaptation of the principle of the pneu-

matic tire. The cushioning effect is secured by means of a cone of heavy fabricated rubber in which is placed an inner tube inflated with air to suit the weight of the driver. The cone and inner tube are placed in a steel air box upon which is set a bucket seat. The whole presses upon a metal knob known as a deflector. The use of the new seat, it is claimed, increases the driver's efficiency.

Publications from the Construction Industry

Steel Joist Construction—TRUSCON STEEL CO., Youngstown, Ohio, has just published a 32-page illustrated data book on the application of and specification for its steel joists. The joists are shown in relation to Hy-Rib lath for floor and ceilings for both wooden floor and cement floor finish. The book contains a considerable amount of tabular

matter on safe uniform loads with various joist spacings, coefficients for deflection, weights of building materials, etc. About a dozen pages are given over to drawings of floor and partition details, balconies, grandstands, roofs, stairways, and framing around openings and in connection with the installation of pipe. Accessories, such as joist clips, screed clips, and hook staples, are shown in application.

Road Graders—RUSSELL GRADER MANUFACTURING Co., Minneapolis, has just published a 64-p. illustrated catalog of its line of road-building equipment, including graders ranging in size from the 5 to the 12-ft. blade type, dump wagons, elevating graders, road drags, scarifiers, wheel scrapers, plows, screens, and crushers. For each type of equipment specifications are given and the various parts, such as blades, wheels, back-slope attachments, etc., are described and illustrated in detail.

Motor Trucks—INTERNATIONAL MOTOR Co., New York, in a 44-p. illustrated pamphlet, presents information on the chain-driven type of Mack truck. These trucks are made with capacities of 1½, 2 and 2½ tons.

Culvert Pipe and Drain Tile—W. S. DICKEY CLAY MANUFACTURING Co., Kansas City, Mo., features its culvert pipe and drain tile for highway and road purposes in a 55-p. illustrated booklet, recently published. The information given includes results of a number of tests of vitrified pipe and special emphasis is given to the company's triple-strength pipe, which, in the 24-in. size, has a wall thickness of 2½ in. and a crushing strength of 6,000 lb. per linear foot. The text gives a number of useful suggestions on culvert construction with particular reference to head walls. A number of pages also are devoted to the Dickey vitrified salt-glazed segment block for sewers, ranging in diameter from 30 to 66 in.

Belting—CHARLES A. SCHIEREN Co., New York, has published under the title "Practical Facts About Belting" a manual on power transmission by means of leather belts. The text includes a discussion of different types of drive, belting rules and ratings, horsepower, care and operation of belts, joining engine belts, alignment, selection of proper kind of belt for the drive, plant layout and shafting.

Cement Roof Tile—AMERICAN CEMENT TILE MANUFACTURING Co., Pittsburgh, in a 64-p. illustrated catalog, explains in detail the design and uses of its Bonanza "Cementile" for roofing of industrial buildings, theatres, auditoriums, railway stations, etc. The product, which is a cement slate reinforced with galvanized wire mesh, is made in three types, interlocking, flat and channel. The tiles are laid directly upon the open roof purlins which are suitably spaced for the purposes. The dimensions of the standard interlocking tile are 26 x 52 x 1 in.; of the standard flat tile, 24 x 96 x 1½ in.; and of the channel tile 18 x 96 in. with 1 in. width of web and 1½ x 3½-in. flanges. In addition to a varied selection of photographs illustrating the uses of the tile for roofing, about half of the catalog is given over to data sheets containing drawings of design details for roofs of different types.

Business Side of Construction

FACTS AND EVENTS THAT AFFECT COST AND VOLUME

Hoover Committee on Seasonal Building Organizes

An immediate survey to determine the facts of seasonal building was laid down as its first task by the Committee on Seasonal Operation of Construction Industries at its first meeting July 11 and 12 at Atlantic City, N. J. It is hoped to have this survey completed and a report prepared this year. As tentatively planned the survey will determine seasonal construction by regions and kinds of structural work, showing the dates of beginning and end of the normal building season for types of work, such as road building, dwellings, apartment and business houses, with the periods of activity and idleness for the different building trades. The survey will also cover seasonal production in building materials, to determine how far this is due to seasonal building operations and trade customs and how far to climatic conditions.

Paving Brick Shipments for June Show Increase

An increase of over a million brick in vitrified paving brick shipments for June as compared with May and a decrease in production are revealed by the monthly report just issued by the National Paving Brick Manufacturers Association from statistics of companies representing 67 per cent of the tonnage of the industry. Shipments in June were 27,251,000 brick as against 26,209,000 for May. June production was 31,105,000 as against 34,382,000 for May. The large number of lettings during the last month and the awarding of many contracts reacted in an increase in unfilled orders of 13,000,000 brick for shipment during the late fall and winter months.

The stock on hand reported shows over 80,000,000 brick.

Of the total shipments in June, 18,630,000 brick went into city streets and 5,631,000 into country highways. The remainder were shipped for miscellaneous uses, such as private drives, factory floors, and general construction.

Ohio led in consumption, closely followed by Pennsylvania, Illinois, Indiana, Minnesota and Texas in the order named.

Construction Materials Contribute to Freight Tonnage

Cement contributed 3,314,168 tons to the freight tonnage of the Class 1 railroads during the first quarter of the current year, figures just made public by the Interstate Commerce Commission show. This tonnage originated as follows: Eastern District, 1,573,435 tons; Pocahontas region, 52,257 tons; Southern region, 361,025 tons; Western District, 1,247,451 tons.

Brick and artificial stone during the first quarter contributed 3,887,171 tons to the amount of freight carried. Lime and plaster contributed 1,214,526 tons. Sewer pipe and drain tile, 424,508 tons.

Structural-Steel Sales

The Department of Commerce announces June sales of fabricated structural steel, based on figures received by the Bureau of the Census in co-operation with the Structural Steel Society. Total sales of 112,735 tons were reported for June by firms, with a capacity of 223,595 tons per month.

Tonnage booked each month by 175 identical firms, with a capacity of 229,575 tons per month, is shown below, together with the per cent of shop capacity represented by these bookings. For comparative purposes the figures are also prorated to obtain an estimated total for the United States on a capacity of 250,000 tons per month.

1922	Actual Tonnage Booked	Per Cent of Capacity	Estimated Total Bookings
April.....	200,588	87	217,500
May.....	184,638	81	202,500
June.....	168,498	73	182,500
July.....	157,631	69	172,500
August.....	156,011	68	170,000
September.....	146,146	64	160,000
October.....	132,450	58	145,000
November.....	111,794	49	125,000
December.....	138,024	60	150,000
1923			
January.....	172,415	75	187,500
February.....	183,938	80	200,000
March.....	218,997	95	237,500
April.....	185,335*	81	202,500
May.....	130,828**	57	142,500
June.....	112,785***	51	127,500

* Reported by 173 firms with a capacity of 229,225 tons.

** Reported by 169 firms with a capacity of 228,850 tons.

*** Reported by 152 firms with a capacity of 223,595 tons.

Canada's Building Permits Decline

According to reports tabulated by the Dominion Bureau of Statistics, there was a decline of 23.6 per cent in the value of building permits issued in Canada in June as compared with May. This decrease, according to the report, is often experienced during June, the largest aggregate of permits granted usually occurring in April or May, when the building season is commencing.

The comparison with June, 1922, also shows less projected activity during the month under review, there being a reduction of 15.9 per cent. Returns received from 56 cities showed that they had authorized building to the value of \$14,345,573, whereas in May, 1923, the total had been \$18,766,065, and in June 1922, \$17,052,582.

Lumber Standardization Progresses

By its action taken at a meeting in Chicago, June 22-23, the Central Committee on Lumber Standards has largely paved the way for a general standardization conference to be composed of accredited representatives from all affiliated organizations interested in the standardization of lumber, to be held at the Department of Commerce in Washington next fall, to take final action on its recommendations, which will be binding on the entire lumber industry.

At the recent meeting in Chicago,

the Consulting Committee on Lumber Standards submitted a number of its recommendations to the Central Committee which were approved with very few changes. Briefly, the recommendations as approved cover standardization of lumber sizes, simplification of grade names, and the guaranteeing of quality and quantity through grading-marking and inspection service. Some of the recommendations are that standard finished yard boards should be not less than $\frac{3}{4}$ in. thick, and that standard finished dimension should be not less than 13 in. thick.

Bids Wanted on Big Jobs

Among projects on which bids are either asked or will soon be called for, in Construction News, pp. 43 to 60, are the following:

Railway, 6-mi., Alabama, from Fairfield to Wenonah, for Tennessee Coal, Iron and R.R. Co., \$4,000,000.

Dam, Merced, Calif., for Merced Irrigation Dist., \$3,000,000 to \$4,000,000.

Home and infirmary, Wende, N. Y., for Board of Supervisors, Erie Co., \$1,500,000.

Coke ovens, Fairport, O., for Koppers Co., \$1,500,000.

Foundation, for two story and basement temple, New Castle, Pa., for Scottish Rite bodies, F. and A. M., total cost, \$1,000,000.

Large Contracts Let During Week

Among the week's announcements of contracts awarded in Construction News, pp. 43 to 60, are the following:

Temple, St. Louis, Mo., to Westlake Construction Co., \$3,000,000.

Grain elevator, Vancouver, B. C., to Northern Construction Co., \$1,600,000.

Weekly Construction Market

THIS limited price list is published weekly for the purpose of giving current prices on the principal construction materials, and of noting important price changes on the

less important materials. Moreover, only the chief cities are quoted.

Valuable suggestions on costs of work can be had by noting actual bidings as reported in our Construction News section.

The first issue of each month carries complete quotations for all construction materials and for the important cities. The last complete list will be found in the issue of July 5; the next, on Aug. 2.

Steel Products:	New York	Atlanta	Dallas	Chicago	Minneapolis	Denver	San Francisco	Seattle	Montreal

Explanation of Prices:—Prices are for materials in carload lots unless other quantities are specified. Increases or decreases from previous quotations are indicated by + or — signs. For steel pipe, the prevailing discount from list price is given: 45-5% means a discount of 45 and 5 per cent. Charge is 15c. per 100 lb. for cutting reinforced steel into 2-ft. lengths or over.

New York quotations delivered, except sand, gravel and crushed stone, alongside dock; common lump lime, in 28-lb. bbl. net, and hydrated lime f.o.b. cars; tile "on trucks"; linseed oil and cast-iron pipe f.o.b. Labor—Concrete laborers' rate, 93c.; building laborers (pick and shovel men) 75c. per hr.

Chicago quotes hydrated lime in 50-lb. bags; common lump lime per 180-lb. net. Lumber delivered on job.

Minneapolis quotes on fir instead of pine.

Brick, sand and hollow tile delivered. Cement on cars. Gravel and crushed stone quoted at pit. We quote on brown lime per 180-lb. net; white is \$1.80 for Kelly Island and \$1.70 for Sheboygan. Common labor not organized.

Denver quotes on fir instead of pine. Cement "on trucks"; gravel and sand at pit; stone on cars; lime, brick, hollow tile and lumber on job. Tile price is at warehouse. Linseed oil, delivered, in iron bbl. Common lump lime per 180-lb. net.

Atlanta quotes sand, stone and gravel per ton instead of cu. yd. Common lump lime per 180-lb. net.

Dallas quotes lime per 180-lb. bbl. Steel, cement, cast-iron pipe and crushed stone f.o.b. cars, other materials delivered.

San Francisco quotes on Heath tile, size 53. Cement, brick, are all f.o.b. warehouses except C. I. pipe, which is mill price

plus freight to railway depot at any terminal. Common lump lime per 180-lb. net. Lumber prices are to dealers in yards at San Francisco, for No. 1 fir common.

Seattle quotes on Douglas fir (delivered) instead of pine. Lump finishing lime per 180-lb. net. Hollow building tile delivered. Hydrated lime in paper sacks. Sand and gravel at bunkers.

Montreal quotes on pine lumber. Sand, stone, gravel and lump lime per ton. Cement, lime and tile are delivered; sand, gravel and stone on siding; brick f.o.b. plant; steel and pipe at warehouse. Hollow tile per ft. Cement price is in Canadian funds (the Canadian dollar stands at 97.45). Bag charge is 90c. per bbl. Discount of 10c. per bbl. for payment within 20 days from date of shipment. Steel pipe per 100 ft. net; 3-in., \$12.84; 6-in., \$108.

Changes Since Last Week

A slight stiffening in the price of common brick at New York, formed the single exception to the general downward trend of materials prices, during the week. Lumber and linseed oil are the two commodities most affected.

Yellow pine timbers dropped 50c. in Dallas and 82¢ per M. ft. in Atlanta, while Douglas fir declined \$2 in Seattle. The lumber movement of the country for the week ended July 14, as reflected by reports from 403 of the larger commercial sawmills, to the National Lumber Manufacturers' Association, gained

materially over the preceding week and the corresponding week in 1922, despite the recent recessions in price. Lumber production for the first twenty-eight weeks of the current year, totaled 6,765,076,783 ft., a gain of 1,116,738,035 ft. over the corresponding period last year. Shipments increased 20 per cent and orders over 13 per cent.

Improvement in pig-iron inquiries developed during the week. Lower iron prices for fourth quarter deliveries, have been checked by the growing firmness of the coke market. Steel bars remain

firm at \$2.40 per 100 lb., Pittsburgh, despite lower pig-iron and scrap spot prices. Slightly better inquiries for structural shapes developed during the last two weeks; quotations remaining firm at the \$2.50 base, with few prospects of lowering. New plate orders fell off slightly during the week. Steel mill operations are slowing down gradually, owing to seasonal influences.

Linseed oil declined 2c. in New York and Minneapolis, 4c. in Denver, 6c. in Dallas and 10c. per gal. in Atlanta, since July 19.

Number 5

The Next Step in Coal

AS THIS is being written it looks as though the leaders on both sides of the anthracite coal industry are going to put to the test the implied threat of government control that was the main feature of the recent report of the President's Coal Commission. Perhaps this is as good a time as any to have this happen. The foresighted consumer, after the hardships of last year's coal shortage, has filled his bins; bituminous production has been heavy and the possibilities of soft coal and other substitutes for anthracite have been given such wide publicity that the user will be more friendly to their use than ever before. If the continued ultimatums and suspensions of conference are merely the usual jockeying of trade and international disputes, the public can wait for a solution without government interference. If, on the other hand, collective bargaining has failed in the anthracite industry, let us proceed at once to the distasteful, but necessary, experiment with government intervention. People are going to get coal when they need it and at a fair price and are willing to try any reasonable scheme which will bring about such a result.

Governmental Accounting

THE net operating deficit of the government-owned and operated Alaska R.R. for the year 1922 was over \$1,053,000, and since operation started in 1915 the total operating expenses have been nine and one-half million against a total operating revenue of two and one-half million, leaving a deficit of slightly over \$7,000,000. In view of a reduction in operating expense of \$100,000 and an anticipated increase in revenue of \$200,000, the deficit for 1923 is expected to be reduced to \$700,000. But there is an item of annual cost which is not included in this governmental statement. That is the interest on the money expended in building the railroad. According to the Department of the Interior, the average cost per mile of the railroad was approximately \$84,000, or a total of something over \$40,000,000, which amount at only 4 per cent interest puts the actual deficit for the year 1922 at about \$2,600,000. These facts are not necessarily condemnatory of the proposition of a government railway in Alaska for obviously no private capital would have gone into this country to open it up without large government grants, and it is highly probable that such grants in a country of vast possibilities in undiscovered mines and great timber resources would have had a value far in excess of the actual capital expenditure made for the privately built railroad. But they do furnish an example of the government method of accounting to the people for the cost of government operation. The figures made public usually account for the actual annual cost of operation and nothing is said concerning the mounting public debt made up largely of capital expenditures on these government projects. On such undertakings as the

Panama Canal and the Alaska R.R. the national benefit forms a large item on the credit side of the ledger but the analogy cannot be carried too far in other prospective government work.

Law Requires Day-Labor Costs

ADVOCATES of force-account construction have an opportunity in the new Breed day-labor law in California to demonstrate their long-urged claim that work done directly costs less by the amount at least of the contractor's profit. By this new legislation all persons proposing to perform public work by day labor are required to file accurate plans and specifications, to record the names of bidders and the prices bid, and to report complete costs of the work and all changes from the plans and specification on file. In the past most argument for or against force-account work has been inconclusive because no cost measure was available for comparison with contract prices. It has been shown in numerous cases and particularly in the investigation by Leonard Metcalf and Harrison P. Eddy a decade ago into Boston city-force-account construction, that rarely are all cost items included in the records. On the other hand in such undertakings as the Panama Canal and the Los Angeles aqueduct, both built largely by day labor, there is reasonable evidence that the method was as cheap as any other, and, in addition, the administration difficulties were greatly reduced. There is such allurements in the thought of eliminating the contractor's profit that popular support can be had to almost any proposal to build public works by day labor. It is hard for contractors to meet this situation by argument because whatever they urge is regarded as prejudiced and, as already said, no costs are available against which they can oppose bidding prices. The new California law puts no obstacles in the way of day-labor methods but it does demand that the people shall be told how much they cost as compared with prices for which contractors were willing to perform the work. Contractors have every reason to be gratified with the new legislation.

"A Passion for Straight Lines"

A FEW weeks ago the New Orleans *Times-Picayune* worked itself into a fine frenzy of protest because in the reconstruction of the East Beach road along the gulf shore at Biloxi, Miss., "stately oaks, growth of hundreds of years, are being sacrificed to an engineering passion for straight lines." To one who knows the beauty of the Biloxi drives, the topography of the gulf coast and the engineering principles that govern modern road construction it seemed unlikely that any such vandalism was being committed but it was thought worth-while to make sure. Now comes word from Edmund Friedman, the resident engineer on the work, that "in a total distance of three miles, eleven trees were cut down, of which only four were sound and of

the four two were directly in the center of the road and the other two so near other trees as to prevent the location of an 18-ft. roadway between." And Mr. Friedman adds: "We realize the beauty of a winding road through trees, especially on a beach front, and have really sacrificed the paving to the trees, instead of the reverse." A small and local matter, perhaps some will say, but it deserves to be emphasized, especially as the *Times-Picayune* has not seen fit to retract or explain its misguided campaign. Every such thoughtless attack makes it harder for engineers to get across to the public that they are solicitous of the amenities of life and not materialists who worship only the practical and who go out of their way to sacrifice beauty to a "passion for straight lines."

Legalizing Licensing

EARLY appeal and a higher court decision on the constitutionality of the Pennsylvania engineer licensing law is most desirable. Judge Shull's interpretation of the law, as outlined on another page, might readily apply to most of the similar laws in other states and if these laws are not in accordance with state or federal constitution, engineers want to know it. The interesting thing in the Shull decision is not that an engineer's licensing law is inherently unconstitutional but that, as written, most of them are. On the basis of the decision a valid law could readily be framed by separating engineers and surveyors and by refusing exemption to any class of engineers. There is a chance for argument as to whether or not an engineer's license law is desirable; certainly there should be no doubt that, with proper provisions, it can be made legal.

Adobe Makes Stable Subgrade

A METHOD of handling adobe soil so as to assure stable foundations for paved roads appears to have been determined with some certainty by the tests of the Pittsburg road near San Francisco. In the final report of these tests, just issued, three of the seven conclusions reached by Lloyd Aldrich and John B. Leonard, engineer in charge and assistant engineer, respectively, relate to results secured from the adobe soil subgrade prepared by sprinkling and rolling the pulverized earth in layers. Not only did this treatment give an unyielding subgrade from the notoriously unstable material of which it was constructed but it is asserted that it gave results superior to broken stone sub-base and also showed remarkable resistance to the absorption of moisture from flooded side ditches. Swelling and cracking, the characteristic behavior of adobe when wet and dry, appear not to have occurred. These determinations are of great practical importance particularly in the light of the statement that the method of preparing the subgrade involved comparatively little increase in cost over prevailing methods. Altogether the determinations at Pittsburg on pavement action were relatively unimportant. Though not negligible the pavement determinations were chiefly confirmatory of the results obtained by the Illinois Division of Highways in testing the Bates road and by the Bureau of Public Roads engineers in the tests at Arlington Farm. On the contrary the adobe subgrade results are original and independent contributions to the research information on road construction.

Some Problems of Negro Migration

THE present migration of negroes from the South to the North is a matter of concern for both sections. Exact figures are not available, but scattered data show that there is going on now a greater movement of negroes away from the South than ever before. That section of the country naturally is alarmed over this depletion of its major labor supply, both for agriculture and industry, while the North, except for those centers that are clearly gaining useful and needed common labor, is not thinking much about the question. To most of those who have given the negro migration any thought at all this movement of population has been considered chiefly, if not wholly, a matter of labor supply; but there are other and possibly more far-reaching effects mainly in the way of public health that both sections would do well to consider.

It would be manifestly ridiculous to rush into any snap opinion as to the proper solution of the negro problem in the South. That is something that the South has been living with for a century and its complications are well known. It can be suggested, however, that this migration menace is only a part of the general problem and it will hardly be solved by the prohibitory legislation some of the states have been considering. The causes spring from economic and social conditions beyond the control of legislative enactment that does not curtail that liberty of movement from state to state that is the right of any and all American citizens. It is to these causes that the South should address its efforts, chiefly by individual and local civic attitude and action.

Consider first and chiefly the matter of health. Many of the negro workers that are coming North bring their families and most of the others will do so earlier or later. That means increase in negro population with its attendant social and health problems. It is a well known fact that, North and South, the general infant mortality rate and the death rate from some of the most dangerous communicable diseases are much higher among the colored than the white. Consequently material additions to the negro population of the North will increase the death rate from all these causes, and some of the mortality causes not merely by the addition of negro population but also by the spread of communicable diseases from negro to white.

By the same means, there will be mortality declines in the South. The actual Southern declines, however, will be affected somewhat by the economic reactions to the northward migration of the negro. Insofar as this migration causes industrial depression in the South and makes living conditions worse than before among the negro residue and the mass of the white population, the depletion of the negro stock will tend to increase mortality; but conceivably the lessened population will not have so hard a struggle for existence as did the original number. At the North, the negro who has migrated there will presumably be under better average conditions than he was in the South. He may find his higher wages largely absorbed by a higher living cost and in general his housing conditions will be far below the ideal, but on the whole he will probably have more, better and safer food, safer water to drink, more chances to bathe, a less polluted soil and far better administration of public health activities, state and local, than in the South.

Aside from its general sociological import, it should be

remembered that this negro migration is only one phase of the present larger matter of immigration restrictions. Both North and South should realize that the American-born colored population is a great national asset, the present value and the future possibilities of which are only beginning to be appreciated. When the negro was the great dividing issue between two sections of the country there was no possibility of a shortage of labor in this country. Foreign white men with potentialities in every field of labor were pouring into the country. There was greater difficulty in finding work for the men than men for the work. Today conditions are the exact opposite. Few potential workmen are coming into the country and the big labor problem is how best to utilize those man resources we already have. The racial and psychological difficulties of the negro problem remain and its historical significance is still great; but with all this it must be remembered that the negro today is an American, with none of the problems of Americanization thrust upon us by that class of foreign born which is so eager to enjoy and yet so ready to abuse American opportunities.

Farm-Bloc Water-Power Economics

GRAY SILVER, the efficient Washington director of the American Farm Bureau Federation—which is the boss of the farm bloc in Congress—has just rendered a report on his year's work. It is a good report, even tempered in the main, mildly and justly prideful of the accomplishments in the way of legislation and worthy of the respect of all who want to see the farmer prosper and get the due which of late years has been largely denied him. So long as Mr. Silver sticks strictly to farming, he follows a straight path; but for a time he wanders in the strange domain of water power and there, under the hypnotic eye of Henry Ford, his steps falter. Interest on investment, according to Mr. Silver, is the curse of water power development. Ford's Muscle Shoals plan leads the way to escape, he says, because by it not only is the interest charge cut in half by the use of government instead of private credit, but by the magic of amortization the whole fixed charge vanishes in time and the user need pay then only for operation. This, says Mr. Silver, is a devoutly to be wished consummation which the farmer must fight for.

Those who see in Mr. Ford just the manufacturer of a good little car wonder why we should confine this idealistic scheme to water power, more particularly to one man's use of one water power. Why not extend it to every line of enterprise? Let any prospective manufacturer, or farmer, or merchant get the government to supply the capital for his plant, or farm, or store, to be paid back in 100 years by his paying 4 per cent interest plus one-tenth of 1 per cent of the capital per year, which latter minute percentage the government each year will invest and continue to re-invest until at the end of 100 years the whole loan has, by magic almost, been repaid.

Except that Mr. Ford, in addition, wants to get for \$5,000,000 what cost the government \$90,000,000, the analogy between his offer and the hypothetical case is complete. Muscle Shoals, under the Ford offer, would not be a public benefit, except insofar as the public is able to buy more cheaply the products that Mr. Ford may make at Muscle Shoals, and in the event, which he does not promise or contract, that he would

be able to manufacture there fertilizer at a lower cost than it is now purchasable. No farmer, or manufacturer, or city dweller under the Ford plan is going to be able to buy power for his own use from Muscle Shoals. It is purely a cheap manufacturing proposition for Mr. Ford plus the possibility—but only the possibility—of a cheap fertilizer.

Mr. Silver's advocacy of this particular scheme is explainable only on the ground that most people believe in a kind of Socialism which extends government aid where it will benefit them and them alone. Or else it is a Utopian conception of this country as another place where people will make a living by taking in each other's washing. Under this scheme the citizens of the United States will divide into two classes, one lending the government money at 4 per cent, the other borrowing the same money back from Uncle Sam at the same rate.

Questions As To Seasonal Building

THE committee organized by the Department of Commerce to investigate seasonal building announced that first it intends to ascertain facts. In so doing it measurably increases confidence in its usefulness. It is presumable that the periods of active and slack building vary both in duration and in the time of year when they occur. Beyond this little is known of their character. There may be and very probably are different busy and idle seasons in Boston and in New Orleans and they may be shorter or longer in one place than in the other. It seems reasonable that the causes also may be different. Certainly cold weather is less a reason for idleness in New Orleans than in Boston. Are there other weather conditions prevailing in the southern city which offset the frosts of the New England metropolis? It deserves to be repeated that we do not know. Facts are needed. The committee cannot be too insistent on this point.

A great deal of our belief in the prevalence and intensity of seasonal building is based on rather nebulous general opinion. In the few instances in which actual determination has been made it has been found that the peaks and valleys of building activity are not so high and deep as they were; that they show less seasonal regularity than they formerly did, and that the causes are apparently more complex than they were once assumed to be. All the evidence indicates that the committee must be more insistent in exacting real facts and not be contented with eliciting general opinion by a few inquiries directed to building department heads.

It is indeed a rather difficult and complex inquiry which the Hoover committee has undertaken and nothing but serious effort will disclose the information which will command the respect of those who borrow and lend money for building. These are the persons who have to be influenced and not contractors and engineers who are merely the agencies for performing the physical tasks.

To what extent does seasonal building construction prevail? What is the character of the variation? What are the causes? With actual facts to answer these questions the building industry is in some sort of position to devise and apply remedies. It is encouraging, as has been said, that the Department of Commerce committee is disposed to seek facts first. Those to whom it will appeal for information should respond with all the labor required to furnish these facts.

Seven Southern States Contemplate Road Expenditures Approaching a Billion Dollars—Automobile License Fees and Gasoline Taxes Will Provide the Money—Editorial Review Based on Studies in the Field

This is the second article of the series. The first article of the series, on Group Problems and the two Carolinas, appeared in "Engineering News-Record" July 26, 1923, p. 128.

The Two Virginias

HIGHWAY development exhibits quite different aspects in Virginia and in West Virginia. The last named has been one of the most prompt of the Southern states adequately to finance and plan a comprehensive state highway system. It has centralized the administration of highways very completely in a state highway commission. A conservative but active construction program has been commenced with attention to the development of trans-state through routes and interstate connections. Virginia on the contrary has been dilatory

out of which, incidentally, system development will slowly come. It will be understood that highway thought, as the term is here used, is thought as manifested by all the acts of the state in highway affairs and not necessarily the thought of the state highway commission or even of the state administration of the moment.

Virginia

Debating Methods of Financing

Highway development in Virginia awaits the decision of a bitter contest over methods of financing road improvement. On one side are the advocates of a pay-as-you-go policy, requiring a construction period of seven to ten years, led by Governor Trinkle. Opposed are the advocates of a \$50,000,000 bond issue and a five-year construction period led by the Virginia Good Roads Association, George P. Coleman, president.

From the press and speakers platform last fall, the debate was carried into the Legislature of 1922-23. Securing no action at the regular session, a special session was called. It met the situation by imposing the 3c. gasoline tax asked by the pay-as-you-go party and by authorizing a referendum vote of the people (November, 1923) on a bond issue as proposed by the advocates of that plan. Now again the battle is being waged in the public press and forum.

Virginia has an area of 43,627 square miles and a population less than 2,500,000. The state system consists of 4,200 miles of road designated as to general routes by legislative acts. Of this system some 1,500 to 1,800 miles—the estimates vary—are classified as reconstructed. Not all of this mileage is permanently graded and only a minor part is highly improved; all, however, has had some sort of surfacing which makes it passable to travel except in distinctly bad periods of weather. In general the system is unimproved in the modern sense of the term improved as applied to roads in the older road-building states of the north. Virginia roads are unqualifiedly "in the mud." This is not said captiously but to make it entirely clear what it means to produce a state system of modern improved roads.

It is a task involving organization, legislation and a comprehensive plan of financing, besides the physical problems of construction and maintenance. All of these processes except financing and construction are well advanced. Even maintenance, with commendable foresight, as will appear, has made progress. There is behind all a strong public sentiment for better highway transportation, as indicated by the advantage taken of the Robertson act privately to finance road construction.

By this act, passed in 1920, any county, district, cor-

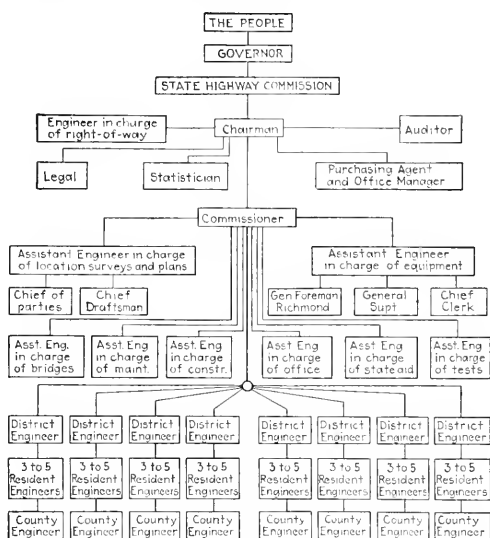

FIG. 3—VIRGINIA HIGHWAY COMMISSION ORGANIZATION CHART

in taking action to finance road improvement and is undecided whether to issue bonds or to build with current funds. Correlated and connected system development and particularly through-route development, are delayed by laws putting the selection of state-road routes and their extension in the hands of the Legislature and specifying simultaneous district and county allotment of improvement funds and operations.

There is a fundamental difference of highway thought in the situations as outlined. West Virginia is thinking primarily toward system development without overlooking local development. In Virginia the thought is primarily toward evenly distributed local improvement

poration or person desiring improvement of any section of state road is enabled to finance the work on the basis that the State Highway Commission plans and directs it, that the money is loaned to the state without interest and that the state shall repay the loan in some indefinite period as funds are available. In the aggregate some \$6,000,000 in funds of this character have been voluntarily loaned to the state to ensure specific new roads which the Commission had no money to build but which the people wanted badly enough to provide the money without interest return for an indefinite period.

This body, recreated by the law of March 24, 1922, which scrapped a mass of confusing legislation, is organized on the basis of the chart, Fig. 3. As stated, little construction has been accomplished. There have been no adequate funds for new work. Maintenance is somewhat adequately provided for by the income of about \$2,500,000 from motor-vehicle license fees. At present the 4,200-mile state system is being maintained and this year patrol maintenance will be so perfected that no road will remain undragged 48 hours after rain or snow. In rapidly developing complete-system maintenance the public is being reached everywhere with highway service and with evidence of the efficacy of centralized state direction.

It is recognized, however, that there can be little fundamental improvement of road service by maintenance alone. Extensive new construction is necessary, and for this large funds must be had. With the 3c. gasoline tax law of March 26, 1923, it is considered by the advocates of pay-as-you-go construction that they are assured. Including all sources of income it is computed that, spread over seven years, nearly \$64,000,000 will be available at the rate of seven to ten millions a year for new construction. The estimated income is from three sources mainly, as indicated by the statement for 1923:

Three cents per gallon motor fuel tax.....	\$2,835,000
Federal Government allotment	1,457,000
State mill tax	1,735,000
State convict road force	350,000
Appropriation out of general fund:	
For construction	200,000
For overhead expenses	285,000
Amount which can be transferred from automobile license tax, after leaving \$2,500,000 out of the \$3,000,000 fund from this source for maintenance.....	500,000
Total	\$7,362,000

For 1929 the total, assuming the natural increase in taxable values, is estimated as \$10,077,000. In these estimates the only unfamiliar item is the credit of \$350,000 for the state convict road force. Virginia's laws provide that convicts shall be employed on road construction on requisition by certain authorities.

The 3c. gasoline tax law was approved March 26, 1923, at the special session of the legislature. At the same session an act calling a bond issue referendum was passed in recognition of the strong faction which considered quick construction with borrowed money a preferable policy to slower construction according to the road money available each year. Between the two plans there is certainty of road construction on an extensive scale compared with anything before known in Virginia. It is the question now whether the people will decide on quantity production with a corresponding saving in construction cost and overhead and earlier returns in highway service or on delayed production with no debt at the end of the production period.

Physically the road construction task is rugged moun-

tain work in the west—the creation of permanent grade from mountain trails. In the Piedmont section, with its higher industrial development, paved and surfaced roads have to be built in rolling, hilly, plateau country. The coastal plain offers a level bottom and swamp-land problem. Broadly the development problem is to open up permanently graded and drained main routes in as large mileages as are practicable. Traffic, except on isolated routes, is light and largely local, and permanent

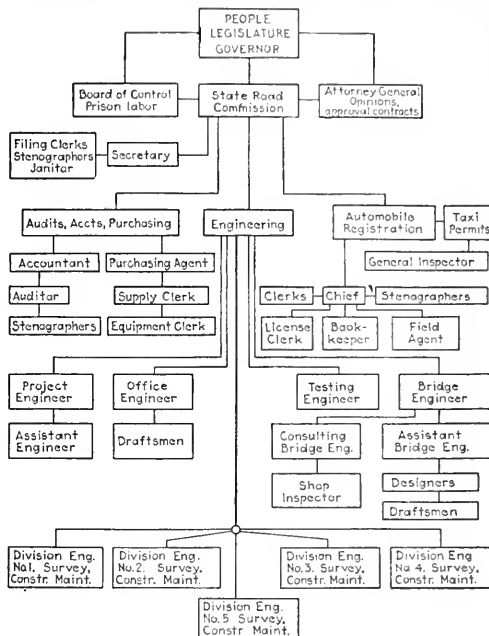

FIG. 4—WEST VIRGINIA HIGHWAY COMMISSION ORGANIZATION CHART

grades lightly surfaced and well maintained are the immediate requirements. With funds provided, the greatest drawbacks to logical system development are the laws requiring simultaneous allocation of funds to construction districts and counties. This makes continuous route development a slow process.

Money will be available for constructing the state road system as now planned. This is the significant conclusion of the situation as it exists. With the sources of income now provided the system can be constructed on a pay-as-you-go plan in perhaps seven years and certainly in less than ten years. If bonds are issued in the proposed amount of \$50,000,000 the construction period will be reduced to perhaps five years. The \$3,000,000 from motor-vehicle license fees turned over primarily to maintenance also assures that the roads can be kept up reasonably well as fast as they are constructed. In two years Virginia has recorded a distinct advance in her highway affairs.

West Virginia

Pushing System Construction

An advanced stage of construction has been reached on its state highway system by West Virginia. With a bond issue of \$50,000,000 provided about the same

Concrete Caisson to Close Canal Against Floating Oil

In Manchester Ship Canal Floating Barrier Is
Provided as Precautionary Measure
in Case of Fire

By R. FRANKLIN MUNDORFF
Kansas City, Mo.

VERY large quantities of petroleum and oils of a flash point not lower than 73 deg. F. have been imported into England via the Manchester Ship Canal, during the last few years. Heretofore, however, the canal company has not permitted the importation of oils and spirits having a flash point below 73 deg. owing to the want of a safe place in which to moor the vessels while discharging their liquid cargoes. This difficulty has now been overcome by the provision of a separate dock and discharging equipment in an isolated situation in which the vessel can be shut off from the canal by means of a floating reinforced-concrete caisson, a precautionary measure in case of fire or escape of the spirit.

The dock is on the estuary side of the canal, while the oil companies' premises and land for future developments are on the opposite side, with road and rail facilities adjoining. The principal dimensions of the dock are as follows: length, 600 ft.; width, 100 ft.; depth of water, 30 ft.; and width of entrance 80 ft. The dock is placed at a convenient angle with the canal to give easy access for the ships, and the approach is provided with two reinforced-concrete dolphins on one side, a recess being provided for the caisson when this is not in use. In each of the main concrete piers at the entrance a vertical groove of a modified V-shape, faced with granite, is provided, and into these recesses suitably shaped projections on each end of the caisson fit, one end being secured by a wedge which is raised and lowered by a winch on the quay.

The foundation of the caisson is to act as a fire-stop at the dock entrance by preventing the escape into the canal of blazing oil in the event of a fire occurring within the dock. The caisson is a box-shaped vessel, nearly rectangular in section, with semi-circular ends terminating in substantial stem and stern posts. The length over all is 82 ft. 6 in., the beam is 12 ft., and the depth from crown of deck to keel is 10 ft. 3 in. The deck has a chamber of 4 in. and the bottom is formed with a fall of 6 in. from the bilges to the keel. A fore-and-aft central wall, together with six transverse bulkheads, divide the caisson into fourteen compartments, separate and watertight. At water level the hull is provided with timber fenders bolted to a reinforced-concrete counter carried by wings springing out from the upper parts of the sides. The total weight of the caisson without ballast is about 125 tons, and its draft is about 5 ft. 6 in. As the working draft is 8 ft. a certain amount of ballast, consisting partly of mass concrete and partly water, is placed in the various watertight chambers to give the requisite flotation.

Each of the compartments is provided with an airtight manhole frame and cover on deck for purposes of access, also a scuttle plug and sounding pipe. The deck equipment comprises two deck winches one near each end, and four cast-iron mooring bits, two on each side of the vessel. For the purpose of adjusting the

water ballast, and also for pumping out any or all of the ballast chambers, each compartment contains a 3-in. sluice valve connected to a 3-in. diaphragm hand pump fixed on deck. Each valve being operated by a spindle terminating in a watertight box, the various compartments can be dealt with singly or any number at a time as may be desired. The stem and stern posts, and also the portions of the "Samson" posts above deck level are sheathed with steel plates $\frac{1}{2}$ in. thick. With the exception of the hull bottom, which is 4 in. in thickness, the concrete throughout the vessel comprising the sides, deck, bulkhead and center wall, is 3 in. thick,

CONCRETE FLOATING CAISSON TO ISOLATE
FLOATING OIL

splayed out at the various intersections. The sides and also the center fore-and-aft wall are stiffened by vertical ribs spaced about 3 ft. 6 in. apart.

The reinforcement throughout the whole of the caisson consists of round mild steel bars of ordinary commercial section. No fabric or steel bars of special form were employed. In the case of the walls, bulkheads and bottoms upon which the pressure might fall from within or without, according to the manner in which the chambers might be charged with water ballast, the reinforcement had to be provided near to both surfaces. The deck, however, only required reinforcing in the usual way for downward pressures. The reinforcement in the floors, walls, bulkheads and deck consists of 1-in. and $\frac{1}{2}$ -in. diameter main and transverse bars suitably spaced and wired together at intersections. Heavier reinforcement, consisting of 1-in. and 1½-in. diameter bars, is introduced in the vertical stiffening ribs, "Samson" posts, stem and stern posts; and also in keel, bilges, gunwales and along the top of the center wall. Whenever necessary, as, for example, in the stiffening ribs, steel stirrups are inserted in order to take up the shearing stress.

The whole of the concrete throughout the caisson is composed of portland cement, sand, and 3-in. (Dalbeattie) crushed granite, mixed in the proportion of 224 lb. cement, 3½ cu.ft. sand, to 7½ cu.ft. granite.

The concrete floating caissons were built by B. Morton & Sons, Manchester, for the Manchester Ship Canal Company of Manchester, England.

Reconstruction of Grandstand at Chicago Ball Park

Winter Work Necessitated Precast Concrete Slabs for Deck—Steel Frame—Old Building Shifted and Enlarged

IN THE improvement of the baseball grounds of the Chicago National League Ball Club (known as the Cubs' Park) for the 1923 season the principal features were: (1) cutting and moving a section of the steel and concrete L-shaped grandstand; (2) building new sections of the grandstand and extending its lower end by fourteen rows of seats; (3) building a deck of precast concrete slabs for the new work; (4) building two bleacher stands 36 x 235 ft. with steel framing and precast slab decks; (5) lowering the grade of the playing field about 7 ft. in order to accommodate the extension of the grandstand. A general view of the work is

FIG. 1—ENLARGING BASEBALL GRANDSTAND AT CHICAGO

shown in Fig. 1, with a layout plan in Fig. 2 and a typical section of the enlarged grandstand in Fig. 3. The additional seating capacity thus provided is 11,000 for the grandstand and 4,600 for the two bleachers, the total capacity being thus increased to 29,300 persons.

Grandstand Design—The original grandstand, erected in 1914 has a structural steel frame with reinforced concrete slab deck, the concrete being poured in place. Columns of steel I-beams spaced 18 ft. 9 in. c. to c. carry inclined 10-in. to 18-in. I-beams, the size of beam depending upon the span. Between the beams are s. ringers of 12-in. channels, to carry the individual slabs of the stepped floor. These old slabs have Ily-rib steel reinforcement with 2 to 3 in. of concrete above the steel and a 1-in. protective coat of cement mortar on the underside. This type of construction was adopted partly with a view to future enlargement and it is reported to have proved very satisfactory in moving, as the structure was very light but yet rigid enough to permit of easy handling.

Transverse steel cantilever trusses carrying the wood

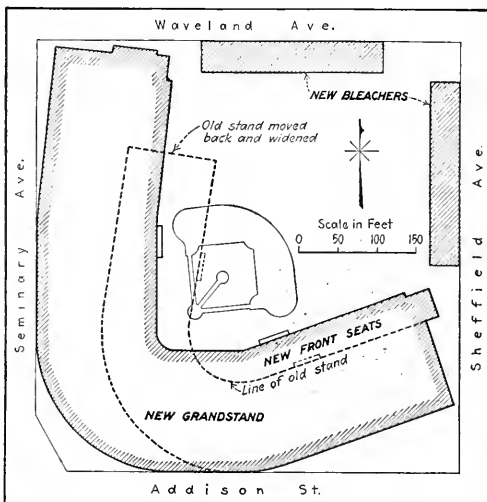

FIG. 2—PLAN OF CHICAGO NATIONAL LEAGUE BASEBALL PARK

roof construction are spaced 18 ft. 9 in. c. to c. and are 90 ft. long, 64 ft. between supports and with an overhang of 26 ft. The rear supports of these trusses are the extended columns of the grandstand. Each alternate truss has a column at the 64 ft. point, the intermediate trusses being supported by longitudinal trusses having a span of 37 ft 6 in. between columns.

In the new parts of the grandstand the steel design is practically identical with that of the older structure. For the 40-ft. extension along the lower side of both the old and new portions the framing consists of inclined 9-in. I-beams spaced 9 ft. 4½ in. apart, supported on concrete posts and carrying stringers of 6-in. channels. The upper portions of the grandstand are reached by means of ramps 10 ft. wide and having a grade of about 12 per cent. The lower portions of the stand are served by stairways 9 ft. wide and spaced an average of 80 ft. apart at two different levels. Those at the lower level are for the additional fourteen rows of seats and the upper ones are at the level of the main aisle, which separates the front or box seats from the grandstand seats. All steel was given two coats of paint after erection. Expansion joints are provided at intervals of about 100 ft. This whole structure, as well as the separate bleachers, was designed for a live-load of 100 lb. per square foot and in accordance with other requirements of the Chicago building ordinance.

Precast Slab Deck—In remodeling the grandstand, practically the entire work had to be done in freezing weather, since the date of the opening game of the season would not permit of any delay. It was decided, therefore, to make the deck of precast concrete slabs which could be handled and placed as required. This arrangement made it necessary to standardize the tie-rod and rivet spacing so that the slabs could be made with the necessary notches and recesses. Close co-operation of the designers of the steel frame and concrete slabs was required in order to secure the correct matching and fitting of the parts.

For the sake of appearance it was not desirable to place the ¾-in. stringer tie-rods below the slabs. Since

the slabs for the greater part of the work are in 2-ft. lengths the tie-rods were spaced 4 ft. c. to c., measuring from the center of each panel, the ends of alternate slabs being recessed accordingly, as shown in Fig. 4. The rivets securing the 2x2x $\frac{1}{2}$ -in. angles on the top flanges of the stringers were spaced 12 in. c. to c. and the underside of the slab was made with recesses to fit over the rivet heads, except at the connections to the I-beams, where countersunk rivets were used. With the slabs in 2-ft. sections and laid in elastic cement no additional provision for expansion and contraction was considered necessary, and the expansion joints in the steel frame are not continued through the deck. Typical construction of the slab deck is shown in Fig. 4.

For covering an area of about 90,000 sq.ft. in the new work a total of nearly 16,000 slabs was required, and these were of 626 different shapes and dimensions, owing in part to the wedge-shaped spaces over the radial stringers and the different spacing of the stringers. These slabs are 2 in. thick for spans up to 3 ft., and 2 $\frac{1}{2}$ in. up to 4 $\frac{1}{2}$ -ft. span all reinforced with No. 12 to No. 9 galvanized wire netting. The majority of the slabs were 2 in. thick and 24 in. wide, weighing 25 lb. per square foot or approximately 150 lb. each.

Each slab has its rear end resting on the lower flange of a stringer, or on a shelf angle riveted to the web in cases where the stringers are laid with flanges turned inward. The outer end rests on an angle riveted to the top flange of the next stringer, the upstanding leg of the angle protecting the face of the slab for its entire depth. To give the necessary slope for drainage a lug or heel is formed under the rear end of the slab. Elastic oil cement was used as a joint filler and was also placed on the angles as a seat for the slabs, the slabs being so placed as to form a squeeze joint. In this way the deck is made practically waterproof, which is particularly desirable in view of the fact that the deck is washed down with streams of water from a hose after every game. Folding seats of theater type are used on the grandstand, the iron legs being secured to the slab deck.

Casting the Slabs—Forms for the slabs were composed of steel frames having two 4x4-in. angles 11 ft. long, connected at each end by a flat bar secured to the horizontal legs by loose rivets so that the angles could be moved together or apart like the bars of a parallel ruler. Bottom boards were placed on the angles, with partition boards or dividers set on edge between them

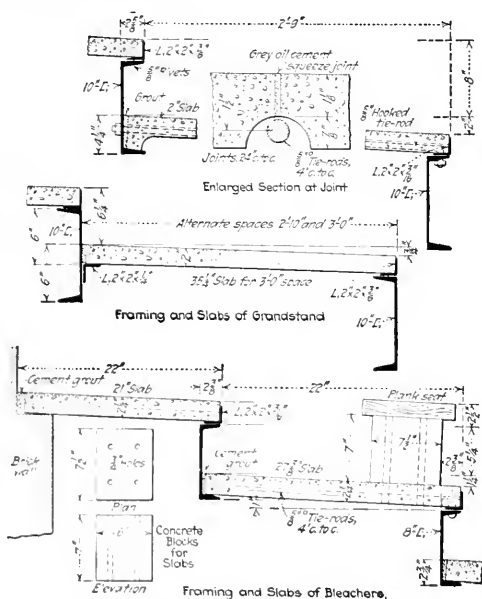

FIG. 4—DETAILS OF DECK CONSTRUCTION

at the required spacing and level with the tops of the angles. The boards were then wedged tightly in place by shifting one of the angles lengthwise. Sheets of the steel reinforcement were then set in place and held at the required height by small concrete blocks. Wet concrete of 1:3 mix, made with gravel of $\frac{3}{4}$ -in. maximum size, was poured into the forms, sprinkled with dry cement and then struck off with an iron bar, giving an even but slightly rough or granular finish.

To form the lug or heel under the higher end of the slab, the bottom board was cut away to the depth required. Special forms were needed for the numerous wedge-shaped slabs of various dimensions. Every slab was numbered to conform to its position as marked on the plans. The slabs were shipped to the park in railway box cars and distributed on warehouse hand trucks. Fig. 6 shows the handling and placing of the slabs. Manufacture was begun Jan. 15 and completed March 3; placing of the slabs was begun Feb. 27 and completed March 28.

Bleachers—For the steel framing of the bleachers, inclined 12-in. I-beams spaced 15 ft. c. to c. are supported by a front footing, a rear wall and two H-beam columns; upon these beams are stringers of 8-in. channels spaced 26 in. c. to c. and carrying the precast concrete slabs. The 4-in. concrete walk at the foot was poured in place, the concrete encasing the lower part of the first stringer. This construction is shown in Fig. 5. For the seats in the bleachers, Fig. 4, single planks

FIG. 3—TYPICAL CROSS-SECTION OF GRANDSTAND

FIG. 5—STEEL AND CONCRETE BLEACHERS

2x10-in. are supported on rectangular concrete blocks spaced about 4 ft. c. to c. Each block has four $\frac{3}{4}$ -in. cored holes, as shown, two for $\frac{1}{2}$ -in. anchor bolts holding the block to the slab and two for bolts to fasten the seat boards.

Moving the Grandstand—Preparatory to moving the two main sections to their new location, the stands were cut crosswise at the proper section and lengthwise just in front of the main aisle. This gave the moving contractors four sections to handle, the largest rectangular section being 80 x 244 ft. All cutting of steel was done with acetylene burners and the light concrete slabs were cut with chisels. The rear northwest section

FIG. 6—PLACING PRECAST DECK SLABS

was moved first, being moved north as far as required, 120 ft., and then west to its new location. By the time the stand section reached this position the lower courses of the footings had been placed. The upper courses with anchor rods and masonry plates were poured after the stand section was in place and before the blocking was removed. The same procedure was followed in the other portions of the stand. After the moving was concluded, an examination of the structure failed to show any cracking of the slabs, or any defects due to moving. For this work each section of the structure was raised by jacks and rolled along tracks of steel rails laid on top of blocking, being moved by means of cables and horse capstans.

Grading the field to its new level was done by a revolving steam shovel. Drainage of the field at its new grade is provided for by a main tile drain starting at the home plate, extending under the second base and across the outfield and emptying into a 9-in. drain at the far end of the field. Lateral drains of 4-in. tile, spaced 12-ft. apart are placed beneath the diamond and

infield, and 4-in. laterals, 25 ft. apart are placed in the outfield.

Speed of Construction—Actual moving of the first section commenced Jan. 10; on Jan. 11 it was in its northern position, a distance of 120 ft.; movement 120 ft. west was started Jan. 14 and concluded Jan. 16. The record time was made on Feb. 8 when the main curved center section, about 80 x 275 ft. in plan, was moved to its new location, a distance of about 90 ft., in two hours. As soon as the first or northwest section was in place, erection of the new steel framework was started, and the old center section was in its new position by the time the erectors were ready to connect to it. Directly after the steel erectors came the cement slab erection crews, which dropped the slabs into place as they moved southward along the stand. The first slab was laid Feb. 27 and by March 15 the grandstand was practically completed. On March 29 the slabs for bleachers as well as for the grandstand were in place, the placing of 14,600 additional seats having been done in 30 days.

Engineers and Contractors—The architect for this work was Zachary T. Davis, with the Westcott Engineering Co. as consulting engineers and designers of the steel framing and concrete work. Lanquist & Illsley were the general contractors; L. P. Friestedt & Co. did the moving of the old structure and erected the steelwork; the Vanderkloot Steel Works fabricated the steel and the Federal Cement Tile Co. made and placed the concrete slabs. All these are Chicago firms.

Some Fallacies on Power Development

Abstract of a paper read before the Southern Appalachian Water Power Conference by O. C. Merrill, executive secretary, Federal Power Commission.

THE popular fallacy that since water costs nothing and runs downhill it can be used to develop power cheaply under any conditions has resulted in proposals to build many water-power plants and in the construction of some that are not economically justifiable. The estimates for many of such developments stop at the generator switchboard, and overlook or ignore the cost of transmission and distribution, and of auxiliary steam reserve. Many also fail to consider the accessories to the actual construction of the dam and power house such as camps, roads, railways, construction equipment, and overhead organization.

Another popular fallacy is that any state can permanently gain at another state's expense through monopoly of its power resources by placing embargoes on the export of electric energy. Such a fallacy overlooks the fundamental fact that we are first a union of states and that our prosperity must be mutual or it does not exist. The federal government as an agent of all the people does not acquiesce in this policy. It has full control over public lands, interstate trade, transportation as an agency of such trade, and over river improvements as needs of transportation. It can construct such improvements at its own expense but prefers to delegate such construction through the agency of the Federal Water Power Act wherever such developments affect public property, which condition applies to most major water-power resources of the country.

Efforts to prevent the development of water-power sites under the Federal Water Power Act on the score of public interest are ill advised. Rates, service, and the issuance of securities and the disposition of excess profits are under federal control and the people are consequently well protected. Moreover the development of water power on many streams by private capital will produce important navigation improvements which would otherwise require large expenditures by the government itself. These items should be considered in any state legislation tending to restrict development under the Federal Water Power Act.

Conclusions Unanimous**

BY FRANK T. CHAMBERS
Captain, C. E. C., U. S. Navy, Washington, D. C.

Special Correspondence

UNDER usual conditions International Congresses of Navigation are held at intervals of three years. The last congress was in Philadelphia in the spring of 1912, so the world war has caused a delay of eight years and an interval between the twelfth and thirteenth congresses of eleven years. This fact and the title of the congress, which would lead the casual reader to the hasty conclusion that the subject matter is only of indirect interest to engineers, justify a brief foreword.

The congresses are in fact of particular interest to all engineers engaged in waterfront construction and river and harbor improvement. They are held under the auspices of the Permanent International Association of Navigation Congresses, which has its headquarters at Brussels, Belgium, and which is supported by contributions from some 36 countries or dependencies, more than 200 corporations or institutions and over 1,500 individual members. The United States, through congressional act of June 28, 1902, became a maximum contributor with an annual appropriation of \$3,000. It thus results naturally that the United States delegates this year to London were selected largely from those departments of the government which are most directly concerned in port development, aids to navigation, etc. Those commissioned by the State Department were Col. J. C. Oakes, Corps of Engineers, U. S. A., vice-chairman, Inland Navigation Section; Capt. Frank T. Chambers, C. E. C., U. S. N., vice-chairman Ocean Navigation Section; Capt. C. L. Hussey, U. S. N., naval attaché, American Embassy; Maj. O. N. Solbert, Corps of Engineers, U. S. A., military attaché, American Embassy. Rear Admiral William E. Reynolds, Commandant U. S. Coast Guard; George R. Putnam, U. S. Commissioner of Lighthouses; Col. E. Lester Jones, director, U. S. Coast and Geodetic Survey; John C. Hoyt, hydraulic engineer, U. S. Geological Survey; Walter Tower, commercial attaché, American Embassy; Capt. W. F. Purdy, operating manager, U. S. Shipping Board at London; Huntington T. Morse, European manager, U. S. Shipping Board, Emergency Fleet Corporation, and W. W. Atterbury, vice-president, Pennsylvania Railroad. Messrs. Jones, Hoyt and Atterbury did not attend.

The program was divided into two sections; the first, Inland Navigation; the second, Ocean Navigation. Each section was subdivided into "Question" and "Communications," the first being given the place of honor, the second, such time as could be spared after disposing of the first. The topics were:

Inland Navigation

Questions—1. Utilization of waterways for the production of power; its consequences and applications.

2. Dispositions or arrangements to be adopted for locks, elevators, inclined planes, and other means of overcoming differences of level with a view to facilitating the operations.

Communications—1. The influence of surface waters and subterranean sheets of water on the flow of rivers. Regime

of mixed canals; estimation of the water consumed for navigation and irrigation uses; the portion returned to the subterranean sheet of water.

2. Unification of statistics of inland navigation with a view to facilitating the comparison of the results of the working of navigable waterways in various countries.

Ocean Navigation

Questions—1. The accommodation to be provided for ships in connection with the construction of new works at ports in order to satisfy the future dimensions of ships.

2. Types of works for berthing ships of great draft in tidal seas.

3. The relative advantages of ship equipment and port equipment for loading and discharging ships. Mechanical equipment of ports. Mechanical handling of freight. Loading, discharging and carrying between ships and the various depositing points whether covered by sheds or not.

Communications—1. Concrete and reinforced concrete. Their applications to hydraulic works; means to insure their preservation and their watertightness.

2. Use of liquid fuel for navigation and its consequences.

3. Utilization of tides for the production of power for the working and lighting of ports and for maritime works (working of lock-gates, etc. . .).

4. Principal advances made recently in lighting, beaconing and signaling of coasts. Standardization (unification) of the languages of maritime signals.

Contributions of papers from the United States were:

First Section—Question 1. Col. William Kelly, Corps of Engineers, U. S. A., chief engineer, Federal Power Commission.

Question 2. Col. Edward H. Schulz, Corps of Engineers, U. S. A.

Communication 1. Prof. Daniel W. Mead, University of Wisconsin.

Communication 2. Dr. Grover G. Huebner, University of Pennsylvania.

Second Section—Questions 1 and 2. Capt. F. T. Chambers, C. E. C., U. S. N., consulting engineer on port facilities, Board of Engineers for Rivers and Harbors, War Department.

Communication 2. Commander Urban T. Holmes, U. S. N. (Ret.), M. Am. Soc. Naval Engineers.

Communication 4. G. R. Putnam, commissioner of lighthouses, Department of Commerce.

Procedure—The meetings of the congress were held in the splendid building of the Institution of Civil Engineers of Great Britain, under the patronage of the King of England. The proceedings were opened with great ceremony, Lord Desborough, President of the Thames Conservancy, presiding and introducing the Duke of York who made the welcoming address. Replies were made by a chief delegate for each principal country or principality represented at the Congress. Col. Oakes responded for the United States. There were delegates from twenty-six subscribing states and four representatives from non-subscribing states, inclusive of Soviet Russia. The Suez Canal company delegated M. Quellennac, consulting engineer, and M. Felix, chief of the technical service. Official delegates were actually present from French West Africa, Belgium, Brazil, Chile, China, Czechoslovakia, Denmark, Finland, France, Great Britain, Greece, Holland, Hungary, India, Irish Free State, Italy, Japan, League of Nations, Monaco, Norway, Persia, Poland, Portugal, Rhine Commission, Rumania, Saar Territory, South Africa, Spain, Sweden, Switzerland, Tunisia, United States of America and Uruguay. There were twenty

British corporations represented, individual members bringing up the total attendance to about four hundred people.

After the opening ceremonies were concluded the registration book was opened, the first signature being that of the Duke of York. Immediately thereafter the sectional meetings were begun and continued throughout the week, the Inland Navigation Section considering and debating the general conclusions, prepared in advance by general reporters, on thirty-nine papers; the Ocean section, eighty-eight papers. The Ocean section attracted about twice the number attending upon the Inland section.

With so many papers it was impossible to read any and resort was had to the conclusions of the general reporters, who, under the rules of the International Association, made definite findings for discussion. The presiding officers, Lord Desborough for Inland Navigation and Sir Ernst Glover for Ocean Navigation, gave the members ample time for discussion, then appointed executive committees to recommend the final conclusions. The system worked well and although it is impossible to say that any new fact was disclosed in these conclusions, it is gratifying to know that whereas methods of construction and equipment, particularly of seaports, differ widely in different parts of the world, these delegates, many of them of international reputation, were practically unanimous in their opinions as to the general principles upon which engineering practice should be based.

Conclusions—The conclusions for Question 1 of the first section dealt upon the necessity for the development of all available water power, under a single control for each country, the development for power to be made in conjunction with and never neglectful of navigation, but bearing in mind also flood control, irrigation, drainage, domestic water supply and fisheries.

For Question 2, the dispositions for overcoming differences of level on canals, etc., it was decided that no precise indications were possible but certain general principles were laid down, scarcely worthy of repetition.

In treating of the first and second questions of Section 2 it was wisely decided that these questions were so intimately related as to require no separate discussion. It was concluded that while there is a general tendency for ships to increase in size due solely to cost of ship operation, without reference to increased cost of port facilities, the depths of the natural harbors and waterways of the world and the cost of providing harbor facilities for quick dispatch of the largest ships should tend to check increase of draft beyond thirty feet; that there will be an increase in the average tonnage of ships between 5,000 and 8,000 tons but not in the tonnage of the largest pre-war ships, in the near future; that while 40 ft. of water has been provided recently for Atlantic liners, the provision for cargo ships has been much more modest; that it will be difficult to justify more than 35 ft. of water at lowest tide for many years to come for other than Atlantic passenger liners, while a port providing 30 ft. of water would be considered first-class.

Concluding the third question the congress expressed a preference for port equipment such as cranes and conveyors rather than to depend upon ship equipment but declared it necessary that ships be equipped with winches, cargo masts and booms, both for use in ports unequipped with booms and hoists and for safety of the

ship itself in cases of grounding or of shifting cargo at sea.

Under the rules no conclusions were drawn on the "communications."

Many of the papers submitted were excellent. Strangely, most of them dealt with only one or two features coming under the particular head, as for instance, types of quay walls under the subject of facilities to be provided for ships. Few took the subject as a whole and analyzed it. Among the papers dealing with one phase only may be mentioned that by Sir Robert Hadfield who, under "Concrete and Reinforced Concrete," took for his actual subject "The Corrosion of Ferrous Materials with Special Reference to Their Resistance to the Action of Sea Water," furnishing not only an interesting paper but a valuable bibliography of his subject. An interesting paper by L. H. Savile, civil engineer in chief, British Admiralty, gave detailed figures to prove his contention that the cost of harbor works increases as the cube of the draft provided. While this can scarcely be possible as a general rule, the paper is well worthy of attention. In fact, while many of the papers are of little value from the standpoint of American practice, there are many good ones and the engineer who possesses a set will prize it highly.

The congress was closed with much the same ceremony with which it opened. Representatives of several countries were called upon to speak. The writer spoke for the United States and was delighted to have the opportunity to thank the British Organizing Committee and the other organizations and agencies who made us all feel at home and otherwise contributed to our profit and pleasure. The way the two chairmen and their secretaries handled our unwieldy convention of representatives of so many nationalities is worthy of all praise.

The social side of the congress was indeed most enjoyable. We were lunched and dined and given receptions and the ladies were taken sightseeing. Particularly charming were the visits to Taplow Court, the beautiful home of Lord Desborough on the Thames, and to Windsor Castle, while the railways and dock authorities were most generous in providing instructive excursions to Southampton, Bristol and South Wales ports, as well as to the Victoria and Albert and King George docks at London.

To Fill Bed of Abandoned Canals in Syracuse

Under a tentative plan agreed upon by the city administration of Syracuse, N. Y., for the disposition of the land pertaining to the abandoned portions of the Erie and Oswego Canals within the city, none of the land will be sold except that upon which there are permanent encroachments. As funds permit, an intercepting storm-water sewer will be built in that portion of the Erie Canal from Onondaga Creek to the easterly line of the city. As fast as the sewer is built the canal will be filled above the sewer to the grade of intersecting streets and the bridges will be removed. A portion of this intercepting sewer work will be carried out at once. The sewer will have a rectangular cross-section above a curved invert, the dimensions being about 10x12 ft. and the grade 2 ft. per thousand. The Oswego Canal will be filled as rapidly as funds are available. A portion of it will be used for an extension of the city market.

Bridges Antedating Christian Era Still in Service

TWO BRIDGES that rank among the very oldest in existence, certainly among the oldest that are still carrying traffic, were recently photographed by P. W. Etkes, assistant district engineer of the Northern District of the Public Works Department of Palestine, resident at Haifa. Both bridges lie on the old highway from Galilee to Jerusalem, and cross the Yarmuk and Jordan Rivers respectively. They were built many years before the Christian era, according to the best available information, but were repaired in later years by the Romans and the Saracens successively. Only a few weeks ago, Mr. Etkes says, he crossed these

Port Officials Act on Equipment Design

THE American Association of Port Authorities, at its meeting of June 12 at Montreal, adopted a resolution the substance of which was that in view of the international character of ocean transportation an effort should be made to bring about greater co-operation in the design of port equipment with the object of making it all as nearly uniform as is possible so that ships calling at strange ports would not encounter cargo-handling equipment unsuitable to their loading and discharging arrangement. A committee consisting of Captain F. T. Chambers, of Washington, D. C., Dr. Brysson Cunningham, of London, and A. D. Swan, of Montreal, was appointed to communicate the substance of this

PALESTINE BRIDGES OF GREAT ANTIQUITY, REPAIRED IN THEIR LATER YEARS BY THE ROMANS AND SARACENS

These structures are still in service. They are to be preserved by the Department of Antiquity of the State of Palestine. The upper view and the view at the right show the Saghir bridge over the Yarmuk River, the two lower views the "Jisr Mujamia" over the Jordan River. The former has a span of 24 ft., and the height from keystone

to water level is 29 ft., while the water is about 25 ft. deep. The Mujamia bridge, which, by the way, has an angle in its alignment just beyond the right end of the main span, has a main span of 41.3 ft. and a clearance of 25 ft. above the water. The water under this span is about 22 ft. deep. The Saghir bridge (upper view) is reported to be 2,000 or more years old.

bridges "in a Buick seven-seater with eight people in it," obvious proof that they are still giving service. New bridges are planned, but the old ones will be preserved for their historical importance. The modern steel bridge near the Saghir bridge, which may be seen in one of the views, is the railway crossing of the Yarmuk in the direction of Damascus.

As may be judged from the pictures, both the foundation conditions and the climate are favorable to long life of masonry arches, and the long preservation of these structures may be in part credited to this fact.

resolution to the principal port authorities throughout the world, and to report their findings to the association at its next meeting. At the time Capt. Chambers received this resolution he was attending the thirteenth international navigation congress at London and he took the opportunity to communicate it to the large number of representatives from the various ports of the world assembled at that congress. The association realizes the many difficulties to be overcome in carrying out such a plan of international co-operation but it expects to get a great deal of valuable information thereby.

Air-Pressure Losses in Piping of Activated-Sludge Plants

Comparative Study of Seven Formulas with Particular Reference to Pipe Layout of Large Plant for Chicago Sanitary District—Relation of Pressure to Pipe-Capacity

By H. L. McMILLAN

Assistant Engineer, Sanitary Division, Sanitary District of Chicago

IN PRELIMINARY studies of air mains and piping for a contemplated large activated-sludge plant for the Sanitary District of Chicago the formula of Fritzsche was used, results being easily determined for various lengths, sizes and flows from a chart of losses of pressure per hundred feet of pipe, prepared by Arthur B. Morrill (reproduced herewith). To compare the Fritzsche with six other recognized formulas the accompanying table of comparative pressure losses under certain

be the case, evidently, by those who developed the formula for ventilating work. The pressure, or the unit weight of compressed air, is dealt with directly in all of the formulas but the Sturtevant, and that one may be considered to have compression factors, as velocity is affected by compression.

All of the formulas, except the Fritzsche, deal with the velocity or quantity of air flowing, raised to the second power, when rearranged in the form $p_1 - p_2 =$

func. $\frac{v^2}{d}$, or func. $\frac{Q^2}{d^5}$, while Fritzsche uses $Q^{1.852}$, similar

to the results of Williams and Hazen in their hydraulic studies, in which they found $v^{1.85}$ as a controlling element, instead of v^2 , and the results of many other investigators on air who found that the exponent varied between 1.75 and 1.95 for air, depending on the kind of pipe used and the quality of its interior surface. (See Mr. Eason's book, mentioned in footnote to table.)

The variation of results of computations by these seven formulas is chiefly due to the coefficient, fixed in some cases and varying in others. The Fritzsche coefficient is fixed, but as he found the pressure loss varied with the 1.852 power of the volume flowing, an average between 1.848 and 1.856, the fixed coefficient is admissible.

The exponent 1.852, compared with the exponent 2, makes a considerable difference in result, especially with large volume of flow.

When developed into terms used in the Fritzsche formula, in which $\Delta p =$ drop in pressure, lb. per sq.in.; $t =$ abs. temp. F.; $L =$ length in ft.; $Q =$ cu.ft. per min., free air at 60 deg. F.; $p =$ abs. pressure, lb. per sq.in.; and $d =$ diam. in.; the comparison is:

Fritzsche,	$\Delta p = \frac{1.268 \ t \ L \ Q^{1.852}}{1,000,000 \ p \ d^{4.85}}$
Wilson & McAdams,	$\Delta p = \frac{1.046 \ f \ t \ L \ Q^3}{10,000 \ p \ d^5}$
Unwin,*	$\Delta p = \frac{5.43 \ f \ L \ Q^3}{100 \ p \ d^5}$
Harris,	$\Delta p = \frac{4.2 \ L \ Q^2}{10,000 \ p \ d^{4.81}}$
D'Arcy,	$\Delta p = \frac{1.125 \ L \ Q^3}{C \ p \ d^5}$
Rix-Johnson,	$\Delta p = \frac{2.5 \ L \ Q^3}{10,000 \ p \ d^5}$
Sturtevant,	$\Delta p = \frac{1.86 \ t^2 \ L \ Q^3}{100,000,000 \ p^2 \ d^5}$
Sturtevant, if temperature is not considered,	$\Delta p = \frac{5.05 \ L \ Q^3}{1,000 \ p^2 \ d^5}$

It should be recognized that the Sturtevant fan formula was developed for ventilating work, etc., at or close to atmospheric pressure, and that the Unwin, Harris, D'Arcy, and Rix-Johnson formulas were developed for compressed air practice, seldom less than 60 or 70 lb. gage pressure, and therefore these five formulas are not strictly applicable to the problem of the moderate pressure of air for activated-sludge plants.

assumed conditions was prepared. The other six formulas are: Wilson & McAdams, Unwin, Harris, D'Arcy, Rix-Johnson, Sturtevant. The last, adapted for ventilation work from the old Weisbach formula, was used in determining pipe sizes for the Milwaukee plant.

Of the seven formulas here considered, only the Wilson & McAdams formula deals with viscosity, through the friction factor f , as a function of z/dvs , when $z =$ the viscosity.

Only the Fritzsche and the Wilson & McAdams formulas deal with the absolute temperature, the Fritzsche directly, as t deg. abs. F., and the Wilson & McAdams through velocity v , specific gravity s , viscosity z , and hence the friction factor f , all of which are affected by the temperature. The Sturtevant fan formula also deals with the temperature, if the velocity v is considered as affected by the temperature, which was not intended to

AIR-PRESSURE LOSSES IN ACTIVATED-SLUDGE PLANT PIPING COMPUTED BY VARIOUS FORMULAS

Slide-rule computations for various diameters, capacities, gagepressures, air temperatures and pipe lengths.

Diameter, in.	60	48	16	12	6	4	3
Capacity, cu ft. per min. free air	90,000	60,000	5,000	2,250	525	150	120
Gage pressure, lb.	7	150	100	100	2.8	1.9	7
Temperature, deg. F.	150	150	100	100	144	104	60
Length, ft.	1,300	910	416	444	164	213	111
Fritzsche	0.100	0.100	0.100	0.100	0.100	0.100	0.100
Wilson & McAdams	0.150	0.147	0.118	0.114	0.103	0.099	0.096
Cool-air pipe	0.111	0.110	0.088	0.087	0.083	0.084	0.081
Unwin	0.097	0.093	0.083	0.080	0.077	0.079	0.098
Harris	0.073	0.075	0.080	0.080	0.077	0.079	0.098
D'Arcy	0.127	0.128	0.127	0.122	0.105	0.094	0.108
Rix-Johnson	0.156	0.148	0.112	0.104	0.084	0.070	0.076
Sturtevant fan at 60 deg. F.	0.145	0.139	0.108	0.098	0.095	0.083	0.071
At temp. spec.	0.200	0.189	0.123	0.111	0.116	0.100	0.071

The pressure losses shown in the table are not for the exact lengths of the various sizes of pipe or conduit, as found in the plant proposed, but are for lengths of each size selected to give results by the Fritzsche formula equal to 0.1 lb. per square inch loss of pressure, so that easy comparison may be obtained. The sizes selected are suitable sizes for the plant, and the amount of air flowing are approximately maximum amounts for each size of pipe in the plant.

The 60-in. size represents a main from the compressor room; the 48-in., a main header feeding many tanks; the 16-in. and 12-in. are branch headers in aeration tanks; the 3-in., the little branch pipes supplying air to the filter-plate boxes. The 6- and the 4-in. are smaller branch headers supplying mixed liquor and sludge channels with air at lower pressure and lower temperature than that in the 48-in. header, such air being drawn from the 48-in. header at various points, and cooled by adiabatic expansion.

The high temperature selected for the large mains is due to probable adiabatic compression with centrifugal compressors, plus friction in compression. The temperature selected for the 16- and 12-in. mains is an approximate average due to cooling within submerged pipes, and that for the 3-in. pipes due to further cooling.

A gage pressure of 7 lb. per square inch is taken for simplicity, representing the pressure of 15 ft. depth of water, plus a small pipe loss and pipe friction. Lower pressure in the 6- and 4-in. sizes is due to their supplying air to shallow troughs and conduits.

The Fritzsche Formula, $\Delta p = \frac{1.268 \times L \times Q^{1.875}}{1,000,000 \times p \times d^{4.875}}$, is developed from

Hütte (d. Ing. Tasch.), where it is given in metric equivalents. In the above form, Δp = drop in pressure, lb. per sq. in.; t = abs. temp. F.; L = length in ft.; p = abs. pressure, lb. per sq. in.; Q = C.F.M. free air at 60° F.; d = diam. in in.

Wilson & McAdams, $p = \frac{0.323 \times L \times v^2}{d}$, in which p = pressure lost, lb. per sq. in.; f = a friction factor depending upon the value of the ratio $\frac{z}{dvs}$; L = length in ft.; s = spec. gr. referred to water at its greatest density; v = velocity, ft. per sec.; d = diam. in in.; z = viscosity, relative to water at 68° F. This formula is given in *Engineering News-Record*, Oct. 26, 1922, p. 690, in which article curves are given, showing values of f , depending upon $\frac{dvs}{z}$ and of z , depending upon temperature.

The Fritzsche formula was developed from extensive tests in which the air velocity varied from 8.2 to 190 ft. per sec., temperature from 57 deg. F. to 239 deg. F., and pressure from 2.9 lb. per sq. in. absolute to 164 lb. per sq. in. absolute; but unfortunately the tests were made with small pipes only.

The Wilson & McAdams formula was developed for any fluid, from data on flow of air, steam, water, various oils, etc., under conditions where the diameter varied from capillary tubes to 36-in. pipes, velocity from 0.1 to 100 ft. per sec., density from 0.075 to 62.3 lb. per cu. ft., and viscosity from 0.02 to 3,000 times as viscous as water at 68 deg. F.

From the curves shown in the table for the values of f in Wilson & McAdams' article, it may be ascertained that for turbulent flow in cast-iron pipe the values of f conform closely to the formula $f = 0.0036 + 0.0063 \sqrt{\frac{z}{dvs}}$, and from the curve for air viscosity the values of z change from 0.0207 at 150 deg. F., to 0.0158 at 60 deg. F., so that from the above equation the

$$\text{Unwin, } p_1 - p_2 = \text{initial and final abs. pressures, lb. per sq. in.} = \frac{0.1005 \times f \times M \times L}{D^5 \times \pi \times \rho} \times \frac{f \times M^2 \times L}{\pi \times \rho \times M^2 \times L}$$

In which p_1 and p_2 = initial and final abs. pressures, lb. per sq. in.; f = friction factor, depending upon the diameter; M = weight of air in lb. flowing per sec.; L = length in ft.; D = diam. in ft.; ρ = average density of compressed air in lb. per cu. ft. This formula is given in "Flow and Measurement of Air and Gases," by Alec. B. Eason (J. B. Lippincott Co., 1919). Mr. Eason gives a table of values of the factor f for diameters from $\frac{1}{8}$ to 36 in., and also gives the formula $f = 0.0027 \left(1 + \frac{6.3}{D} \right)$, where D is in feet.

Harris, $f = C \frac{L \times v^2}{d^5 \times p}$, in which f = loss of pressure in lb. per sq. in.; L = length in ft.; v = cu. ft. per sec. of free air; d = diam. in in.; C = ratio of compression in atmospheres; and C = coefficient containing all constants. This formula is given in "Compressed Air," by Elmo G. Harris, 1917, p. 50, as a fairly approximate formula, not as an exact one, however. Prof. Harris finds that the coefficient C depends upon the diameter, as $\frac{0.1025}{d^{0.31}}$, hence the equation can be written $f = \frac{0.1025 \times L \times v^2}{d^{5.31} \times p}$. Harris gives values of the coefficient for sizes up to 12 in., which could be developed further, but the computations do not require it if the latter form of the formula is used.

$$\text{D'Arcy, } D = C \sqrt{\frac{d(p_1 - p_2)}{w_1 L}}, \text{ or, } p_1 - p_2 = \frac{D^5 w_1 L}{C^2 d^5}$$

In which D = cu. ft. per min. of compressed air at final pressure p_2 ; C = a coefficient depending upon diam.; p_1 and p_2 = initial and final abs. pressures, lb. per sq. in.; L = length in ft.; d = diam. in in.; w_1 = density of air in lb. per cu. ft., at initial pressure p_1 . This formula is given in "Air Compression and Transmission," by H. J. Thorkelson, 1913, p. 173, and values of the coefficient C are given for 1- to 12-in. pipe. By plotting values of $\frac{D^5}{C^2}$ as the coefficient is used, and smoothing up the curve a little, and extending it, values of C were obtained for the 16-, 18- and 60-in. sizes, approximately, of course. The formula is also given in "Compressed Air Plant," by Robert Peele (John Wiley and Sons, 1913), p. 251, and in Kent, 1903 Ed., p. 439, as "a common formula for flow of air, gas, or steam in pipes," but is there given without any values of the coefficient C . Thorkelson makes no comment on the derivation of the formula. Peele specifies it as D'Arcy's formula.

Rix-Johnson, $p_1 - p_2 = \frac{0.0005 \times V^2 \times L}{d^5}$, in which p_1 and p_2 are initial and final abs. pressures, lb. per sq. in.; V = cu. ft. per min. free air; L = length in ft.; d = diam. in in. This formula is given in "Compressed Air Practice," by Frank Richards, 1913, p. 174, as Johnson's development of Church's formula, modified by Rix. Richards states that this formula gives results which are approximately correct in practice, and advises limiting the velocities of compressed air to 25 ft. per sec.

Sturtevant, $p = \frac{L \times v^2}{25,000 \times d}$, in which p = pressure lost in oz. per sq. in.; L = length in ft.; v = velocity, ft. per sec.; d = diam. in in. This is the old Weisbach formula, revised, used by the B. F. Sturtevant Co. as a fan formula for ventilation work, etc.; it is given, as such, in Kent, 1903 Ed., p. 487, and in Prof. Thorkelson's book in a quotation from "Fan and Ventilation," by H. delz, Parsons. It was developed for ventilating work rather than for compressed air, and has no compression or temperature factors, except as introduced by the user in order to obtain the real velocities in the pipes.

value of f would change but slightly with this viscosity difference, showing that, in the case of air, the element of viscosity has slight effect upon the loss of pressure, especially in the large pipe sizes.

Considering the question of varying the pipe diameters to get the same computed pressure loss by each of the seven formulas, in the case of the largest flow considered in the table below, the Fritzsche formula, for 0.100 lb. loss, requires 60-in. size; Wilson & McAdams would require 65-in. for cast-iron pipe, 61 $\frac{1}{2}$ -in. for copper pipe; Unwin, 59.6-in.; Harris, 56 $\frac{1}{2}$ -in.; D'Arcy, 63-in.; Rix-Johnson, 65.6-in.; and Sturtevant, 64.6-in. at 60 deg. F., and 69-in. computed at 150 deg. F.

In view of the great cost of pumping air for large activated-sludge plants, it is important to save all of the loss of pressure possible, to make a proper balance between economy of construction and economy of operation. It has been estimated that for each 0.1 lb. per sq. in. of pressure saved, at the proposed plant of the Sanitary District of Chicago, a saving of about \$3,000 per year in cost of power will result, which would

warrant considerable increase of size of piping to decrease the pressure loss.

Investigators can do considerable service in checking up pressure losses in large piping, within the range of pressures used in activated-sludge practice, with the view of establishing the correctness of the formulas, or proper variations due to roughness of pipe surface.

Declares Pennsylvania Licensing Law Unconstitutional

Violates State Constitution in Treating Two Subjects and Federal Constitution in Being Discriminatory

IN THE Court of Quarter Sessions of Monroe County, Pennsylvania, Judge Samuel E. Schull on July 2 rendered an opinion that the Pennsylvania state engineering licensing act was unconstitutional. The case came before the court as the interpretation of a special verdict rendered by a jury in the complaint against George E. Stevenson, of the long-established engineering firm of Stevenson & Knight, of Scranton, Pa., who was arrested in June, 1922, charged with practising the profession of land surveying in Pennsylvania without having first obtained a license as required by the act of the Pennsylvania Assembly of May 25, 1921, Public Laws 1131. The procedure in the case was that the jury was instructed to render a special verdict which returned the decision to the judge on the question of the constitutionality of the act. The judge declared the act unconstitutional on three grounds.

He said it was in violation of Article 3, Section 3 of the Constitution of Pennsylvania, which provides "No bill, except general appropriation bills, shall be passed containing more than one subject, which shall be clearly expressed in the title." In this case the act bears the title "An act to Regulate the Practice of Professions of Engineering and Land Surveying, etc." The judge said that in view of the article of the constitution of Pennsylvania quoted, the question now was whether the professions of engineering and land surveying are distinct and independent or cognate branches of one subject. In considering this he quoted the section of the act which includes in its control "any person practising or appearing to practise the profession of engineering or land surveying." Thus, according to the judge, in the very beginning of the act the two professions are recognized as separate and distinct and throughout the entire text they are so recognized and treated, the professional engineer and the land surveyor being defined separately. The judge said that under the provisions of the act a registered engineer may not practise as a land surveyor nor may a land surveyor practise engineering, thus again marking or recognizing the distinctiveness of the two professions. Further than this, the judge called attention to the fact that the avowed purpose of the act is "to safeguard life, health, and property," and said "The relation of engineering to this purpose is, of course, apparent, but how it is related to the dissemination of area of land, the establishment of boundary lines of land and the subdivision or plotting thereof is beyond our conception."

The judge further notes that even in the profession of engineering the act makes certain exceptions, particularly as to officers and employees of the government of the United States and of the State of Pennsylvania and

the officers and employees of a corporation engaged in interstate commerce. Thus, said the decision, "the qualification of the engineers who plan our railroad projects is left to the discretion of the office of the railroad company employing them, while, on the other hand, a land surveyor who runs a line and figures the area of a town plot on which the public has not the right of entrance must submit his qualifications to the board of engineers and be subject to their caprice as to whether or not he may engage in that character of business." In view of these contentions the judge decides that the act violates the state's constitution on account of dealing with two professions and the fourteenth amendment of the federal constitution in that it is discriminatory in the exemption of certain classes.

Further than that the judge contends that the section of the act which states that it shall be unlawful for the commonwealth, or for any county, city, borough, town, township, school district, or poor district to engage in the construction of any public works involving engineering unless the plans, specifications and estimates have been approved by and the construction supervised by a registered professional engineer, is in effect an act regulating public works and has no business in an act relating to the regulation of engineering.

In view of these facts he held that the act was unconstitutional and therefore prosecution under it cannot be sustained and on the special verdict of the jury he found the defendant not guilty.

Railway Improvements Cost 1½ Billions

Railway expenditures for improvement work and new equipment during 1922 and 1923 will represent a total of \$1,540,214,000 according to figures compiled by the Bureau of Railway Economics and submitted at a conference of the American Railway Association with the Interstate Commerce Commission. Of this great total, 60 per cent is for equipment and 40 per cent for improvement works. In the latter class, track expenditures are far in the lead with a total of \$237,429,000; shops, enginehouses, machinery, stations and docks come next with nearly \$123,000,000; bridges and tunnels, \$70,458,000; freight yards and water and coaling stations, \$46,764,400; grade reduction, line revision and grade crossing elimination amount to \$42,204,400. The itemized figures are given in the accompanying table:

Track	\$172,564,398
Heavier rails	44,032,531
Additional ballast	16,378,947
Roadway machinery and tools	4,453,200
Bridges, trestles and culverts	60,010,400
Tunnels, subways and viaducts	10,425,700
Shops, enginehouses, machinery and tools	70,397,120
Stations and office buildings	33,365,500
Storehouses, elevators, coal and ore docks	14,411,500
Wharves, docks and piers	4,093,300
Classification yards	25,517,500
Water stations	13,537,300
Coaling stations	7,709,600
Grade crossing elimination and protection	21,781,700
Grade and curve reduction	20,425,700
Signals and interlocking plants	14,193,400
Telephone and telegraph lines	5,701,600
Electric power plants and transmission lines	5,592,900
Purchase of land and buildings	10,778,500
Miscellaneous	61,203,116

Total improvements

Locomotives	\$238,615,936
Freight-train cars	593,201,831
Passenger-train cars	63,319,005
Other equipment	22,383,363

Total equipment

Total improvements and equipment.....

Depreciation; a Definition

BY CHARLES HANSEL
Consulting Engineer, New York City

A *COMPOSITE* Property is one composed of two or more simple properties each of which can be replaced independently.

A *Simple Property* is one complete in itself—though in some cases possible of repair, which cannot be replaced practically by piecemeal but which should be replaced as a whole.

Depreciation as applied to a composite property, such as a transit company, is only that part of deterioration of the physical elements, if any, which has not been but which should have been restored seasonally or periodically in order to maintain an appropriate standard of operating efficiency.

Deterioration is the lessening of the useful life of a simple property due to impairment from any cause. It is subdivided into *permissible deterioration* and *depreciation*.

Permissible Deterioration or *Decretion* is that part of deterioration which has not been and which should not be made good because it has not reduced the property below an appropriate standard of operating condition.

The elements of the physical property of a traction property subject to deterioration are shown in the diagram attached, as in a state of flux, in a "U"-shaped tube, open at both ends, resting on the non-depreciable elements.

The solid portion of the tube shows the elements which deteriorate, kept at 100 per cent efficiency. The left leg above level *B* represents appropriate "deterioration." To keep a level of 100 per cent operating efficiency above 80 per cent of new would be economic waste; for, as illustrated by the right leg of the tube, the putting in of elements (money) at *A* will, so long as the level *B* is maintained, result in wasting at the level *B* without increasing operating efficiency. The deterioration from level *A* to level *B* should not be recouped by appropriate maintenance, but should be included in Rate Base.

Level *B* (20 per cent below level *A* or 80 per cent new of the elements which deteriorate) is the constant average condition above which it would be economic waste to attempt to maintain. It is the level of 100 per cent efficiency and stable condition. Unless this level is permanently lowered, no deduction should be made from condition new in fixing the amount upon which the owner should receive a reasonable return.

Level *C* is shown 35 per cent below condition new or 65 per cent new of the elements which deteriorate. This level *C* may properly be temporarily reached during the cycle of seasonal or periodical periods and does not necessarily indicate insufficient maintenance. If,

however, this level is not seasonally or periodically raised to *B*, then the operating efficiency falls.

If level *C* is allowed permanently to remain, the owner having received in payment for service a sum sufficient (1) to give him a reasonable return on the value new, (2) to maintain the property at 100 per cent efficiency—i.e., level *B*; then, the owner should, at his own expense, bring the property back to level *B* and this cost should not be included in the Rate Base.

In using 80 per cent of new as the level of 100 per cent operating efficiency for the purpose of illustration, it should be understood that this per cent varies according to the requirements of operation. Some properties may be above and some below 80 per cent of new and yet be in 100 per cent operating condition for the service required.

Sacramento Paid for One-Third Weight-Gain of Garbage-Fed Hogs

PENDING the construction of an incinerator, the city-collected and delivered garbage of Sacramento is being fed to hogs on a 10-acre city-leased tract, 2½ miles from Sacramento, by a contractor who pays the city for one-third the net-weight gain of the hogs while they are being fed on garbage.

The wagons dump the garbage on the feeding ground, where it is spread out for the hogs by one or two attendants. Combustible residue is burned from time to time. The contractor must put the land in shape after hog feeding is abandoned. H. C. Bottorff, city manager of Sacramento, states that in June of this year about 700 hogs were being fed and that the city was receiving an average of some \$450 a month as its share of the net weight-gain of the hogs. The hogs are weighed in and out, and monthly payments to the city are based on the public weighmaster's slips. This feeding plan was practiced about six weeks in the fall of 1922 but was stopped temporarily when wet weather made the road to the hog farm impassable. Feeding was resumed April 15 and will be continued until this fall, when it is expected that a new incinerator will be in operation. The amount of garbage ranges from some 60 tons in winter to 80 in summer. The population of Sacramento was 65,908 in 1920 and 44,696 in 1910.

Despite the fact that hog feeding is believed to be the most profitable form of garbage disposal, Sacramento city officials believe that it would be impracticable to continue this method of disposal long in view of the rapid settling up of territory adjacent to the city, which would make the operation of a hog farm objectionable at any point within economical hauling distance.

Appeal to Builders to Buy Out of Season

Franklin D. Roosevelt, chairman of the American Construction Council, has appealed to the building construction industry to buy as much material off season as possible, so that the railroads will not be swamped with building materials during the early part of the building period each year. He called attention to the practice of the American Radiator Co. of offering special discounts for deliveries made during off months, and recommends that this policy be followed by other concerns.

Tests of Five Models of Draft Tubes for Turbines

Made with Turbine and Tubes Geometrically Similar to Full-Sized Ones—New Symmetrical Type Superior to Older Forms

ONLY within recent years has it been realized that the setting of water wheels is almost as important as the design of the wheel itself in obtaining a maximum efficiency over a wide range of loads. In 1900 the largest wheel installed was of 5,000 hp. capacity and had an efficiency of about 63 per cent at 50 per cent of its rated power and an efficiency of 80 per cent at 100 per cent of its rated power, with the efficiency curve inclining sharply upward, indicating that the maximum would be obtained at considerably above the rated capacity of the machine, a point where the turbine was not intended to operate. Since that time improvements in the design of the runner as well as in the method of setting the wheels have made such strides that the efficiency of the 37,500-hp. unit installed by the Niagara Falls Power Company in 1919 and 1920 was 90 per cent at about 50 per cent of the full load, and also at the full load, and obtained a

maximum efficiency of 93 per cent between 70 and 85 per cent of the rated load.

The straight-type draft tube was one of the developments which took place during the study of the turbine setting, but it was soon found that the cost of excavation necessary for such draft tubes was excessive. This led to the adoption of a bent type of tube. These bent tubes materially reduced the cost of installation, but were found to be seriously defective when efficiency was considered. In view of this fact and the fact that a gain of only a fraction of one per cent in efficiency of the output of the great modern turbines gives a large increase in output for a given amount of water, a great deal of careful study has recently been given to the development of symmetrical types of draft tubes that would regain both the axial and tangential components of the flow, and do so without excessive excavation cost.

The tests are reported in detail as follows in *Power*:

One of the symmetrical types is the hydracone regainer developed by William M. White, manager, Hydraulic Department, Allis-Chalmers Co. Another type is the so-called spreading draft tube developed by Lewis F. Moody, consulting engineer, I. P. Morris Department, William Cramp & Sons Ship and Engine Building Co. In the latter the water passage is an annular space between an outer flar-

FIG. 1—RELATION BETWEEN EFFICIENCY AND HORSEPOWER OUTFIT

These curves represent the complete turbine under a given head at whatever speed is secured under the best conditions with each draft tube. They were approved and signed by H. Birchard Taylor, vice-president, Cramp Co.; Hugh L.

Cooper; and Maj. Gen. Lansing H. Beach, Chief of Engineers, U. S. Army. The cross-section of the runner shown on this figure is not the Muscle Shoals, but has about the same specified speed and indicates the D_2 dimension.

FIGS. 2 TO 5—FOUR OF THE DIFFERENT TYPES OF DRAFT TUBES TESTED

Fig. 2—Sections through a symmetrical type of tube indicated as No. 11 on the curves. Fig. 3—Sections of a bent draft tube with a spiral baffle shown as No. 12 on the

curves. Fig. 4—Sections through new type of bent draft tube and shown as No. 15 on the curves. Fig. 5—Sections through spreading type of draft tube indicated as No. 14.

ing wall and an inner core, in which the axial components of flow are gradually turned in the radial direction and at the same time are continuously reduced in magnitude.

When the designs were laid down for the government hydro-electric development at Muscle Shoals, a draft tube of the Moody spreading type was adopted from this particular installation by Hugh L. Cooper & Co., consulting engineers on this project. This type at that time was shown by tests on models to be the most economical from both an engineering and a financial viewpoint. Since then the development in draft-tube design has brought out other types that merited consideration, since under test for cer-

tain conditions they apparently showed the possibilities of a reduction in cost of construction sufficient to offset the difference in efficiency, as compared with the type adopted for the first four units to be installed at Muscle Shoals. This led to a series of tests being ordered by Maj. Gen. Lansing H. Beach, Chief of Engineers, U. S. Army, to be conducted on various types of draft tubes in the I. P. Morris laboratory for the War Department, under the supervision of Hugh L. Cooper & Co., consulting engineers. The purpose of the test was to secure a comparison of performance between types of bent tubes of simple design and comparatively easy and cheap to construct and some of the more

recent types which are highly efficient but involve expensive reinforced-concrete construction.

Model of High Specific-Speed Runner Tested—Tests were made of a model of a complete turbine equipped with a high specific-speed runner of the usual mixed flow, or so-called Francis type, similar to the 35,600-hp. units to be installed at Muscle Shoals, and with draft tubes geometrically similar to those that would be used in this installation. All parts of the turbine, testing flume and testing equipment remained the same in each test with the single exception of the type of draft tube provided, and each tube was designed to come within the same space restrictions. Tubes of five types were tested. These are shown on the curve sheet, Fig. 1, and in Figs. 2 to 5. No attempt was made to prove that one type was more efficient than another except for the condition in question.

Fig. 2 shows sections through a symmetrical type of tube indicated at No. 11 on the curve. As indicated by section AA, this tube had a vertical baffle that extended

COMPARABLE SPEEDS—FROM CURVES BASED ON THE SAME MAXIMUM CAPACITY OF TURBINE

Draft Tube No.	Design	Speed With No. 11 Tube as Base or 100 per Cent
11	Symmetrical tube (H. L. Cooper design No. 1)	100 per cent
15	Non-symmetrical tube (Alabama Power Co. design)	108 per cent
14	Symmetrical tube with cone (Moody spreading-draft tube)	115 per cent
—	Without draft tube	101 per cent
12	Quarter-turn tube with spiral baffle (H. L. Cooper design No. 2)	109 per cent
12	Quarter-turn tube without spiral baffle (H. L. Cooper design No. 2)	107 per cent
13	Symmetrical tube with lateral diffuser (H. B. Taylor design)	102 per cent

well up into the neck of the tube, otherwise the construction was similar to a short conical type with a vertical pier in the center of the horizontal discharge section. As might be expected, this tube showed up poorly in efficiency, probably owing to the short length of the tube and the baffle directly under the discharge from the turbine, causing turbulence which prevented the water from flowing readily from the tube.

In Fig. 3 are given sections of a bent tube with a baffle in it. This baffle might be considered as an extension of the vertical pier in the horizontal section of the tube, which is given a 90-deg. turn as it approaches the bottom of the turbine's casing and extends up to within about three inches of the runner. At this point it is reduced to a thin edge at right angles to the pier in the horizontal section of the tube. This type of tube with its 90-deg. spiral baffle showed considerably better results than design No. 11, between 50 per cent load and normal rated power of the turbine. However, below 50 per cent load the efficiency fell off rapidly and showed a lower efficiency at light loads than any of the other types tested. Tests were made on this tube with the spiral baffle and the pier removed, which made the tube similar to the ordinary bent type. Under this condition from about 60 per cent full load to normal rated capacity the efficiency is lower than with the baffle. Below 60 per cent load the efficiency holds up better than with the baffles and from 50 per cent load down shows a better efficiency than any of the other types tested.

Design No. 15 is of a type similar to that developed for the Mitchell Dam project of the Alabama Power Co. and is shown in section in Fig. 4. The curve of this type falls in an intermediate position in regard to those of the other types. Although in these tests this tube shows a lower turbine efficiency by about 2 per cent than model No. 14, which is the Moody spreading type, on a prior test made at Worcester, Mass., on a tube of a design similar to No. 15, and under conditions similar to those at Mitchell Dam the difference in efficiency was not so great. In fact, the results of the Worcester tests led to Hugh L. Cooper & Co.'s carrying on the tests at the direction of the War Depart-

ment to make sure that the advance in draft-tube design had not produced a type more economical than that available at the time the Muscle Shoals project was first decided upon.

Two sectional views of a model of the type of spreading tubes to be used at Muscle Shoals are shown in Fig. 5. Between 40 per cent and 100 per cent load, or throughout the usual operating range, this tube shows better turbine efficiency, does this with the turbine operating at a higher speed, and the turbine develops from 6 to 14 per cent more power than with any of the other types.

A test was also made on a model tube having a lateral diffuser as shown at 13, Fig. 1. This arrangement gave an efficiency inferior to some of the other models. Each curve represents the run secured under the best conditions for that tube.

Referring to Fig. 1, the curves represent the relation between the total efficiency and the horsepower output of the complete turbine under a given head at whatever speed is secured under the best conditions with each draft tube. The curve shown in dotted lines represents the performance of the turbine without any draft tube. In this test the runner discharge passed into a wide chamber, the discharge from this chamber being submerged below the tail-water surface so that there was no loss of static head on the turbine. The difference in turbine efficiency of 7 per cent and over 19 per cent in power capacity shows clearly the effects of equipping the turbine with an efficient type of draft tube.

The curves show that with a turbine designed for a suitable power output and a suitable speed, the spreading draft tube would exceed the others not only with respect to peak efficiency, but also for efficiencies at powers throughout the ordinary operating range; namely, from 40 to 99 per cent of the rated full load.

It might be mentioned that draft tube No. 14 was tested both with a high cone, as indicated on the curve, and with a somewhat lower cone, and the comparison resulted in favor of the high cone, although the difference was not great in this case. The advantage, however, of the higher cone in most installations is that it results in higher efficiency and also produces quieter and steadier conditions of flow. In the ordinary types of draft tube the center is occupied by turbulent water not partaking of the general stream-line flow, and under extreme conditions there may be a cavity filled with air or vapor at this point, a condition which is removed by filling this region with a solid core. This arrangement not only eliminates certain internal conditions, but also, through the removal of inertia effects in the center of the draft tube, prevents them from being transmitted to the penstock, which in some installations has resulted in water hammer or surging involving pressure rises as high as 25 to 35 lb. per sq. in. The 70,000-hp. units being built for the Niagara Falls Power Co. will be equipped with draft tubes with the cone extending to the runner. The same remark applies to the new 58,000-hp. unit No. 6 for the Queenston station of the Hydro-Electric Power Commission of Ontario. The use of a cone even of moderate height in the draft tube has shown a marked effect in producing steady conditions and in preventing inertia effects, and apparently the logical procedure is to run the cone to the runner.

These tests represent a contribution to a phase of turbine design which in the past has been neglected. When we consider the effort that has been expended on the part of the hydro-electric industry to secure increases in turbine efficiencies of fractions of one per cent by improvements in runner design, it is manifest that improvement in the efficiency of the turbine as a whole by improving the draft tube is equally important. The draft tube of a turbine must be designed to take care of a complex condition of flow, and each installation requires special treatment and study, and it cannot be said that results arrived at in one condition are applicable to another without giving the particular flow involved in the draft tube due consideration.

Waltham Reservoir Waterproofed by a New Lining

Disintegration of the Reinforced Concrete Due to Seepage and Frost Action Makes More Waterproofing Necessary

By M. W. FISHER

Engineer, The Texas Co., Asphalt Sales Department, New York City

IN SPITE of the elaborate precautions taken at the time of construction to make the concrete in the Waltham, Mass., reservoir watertight, both by careful proportioning and the addition of integral waterproofing compounds, it has since developed so much seepage that it has been necessary to resort to additional waterproofing to save the structure from disintegration due to frost action. This has been successfully accomplished by relining the sides of the reservoir.

The standpipe was built in 1906. (*Engineering Record*, Jan. 12, 1907, p. 32.) It is 100 ft. in diameter, 43 ft. high, and has a capacity of 2,000,000 gal. The side walls are of reinforced concrete 18 in. thick at the bottom, rising with a constantly battered outside face to a 12-in. thickness at the top. The concrete was carefully proportioned to obtain the best mechanical mixture for the filling of the voids, and hydrated lime in the proportion of five per cent of the weight of cement was added to it. The first 10 ft. of the inside wall was plastered with mortar containing an integral waterproofing compound, and the remainder received at least two brush coats of a similar mixture. (*Engineering News*, Sept. 19, 1907, p. 310.)

In 1914, an ill-advised attempt was made at waterproofing by the application of a coat of pitch to the inside wall. This amounted to very little and another attempt was made shortly afterward by the application of cement, using a cement gun, on the outside. Neither of these methods proved satisfactory, the seepage continued and successive frost action caused several large areas of the outside wall to disintegrate, the surface breaking in several places to such an extent that the reinforcing rods were exposed.

During the summer of 1922 it was decided to reline the reservoir. After the contract for the waterproofing had been let and all details arranged, the standpipe was emptied and the inside wall thoroughly cleaned and dried, a number of salamanders being used to hasten the drying. When the walls were thoroughly dried, the waterproofing was started. It consisted, first, of a mop coat of Texaco No. 56 waterproofing material applied hot to the inside face of the wall. Immediately over this was applied a coat of waterproofing felt, the surface of the same being mopped with another coat of Texaco No. 56 waterproofing asphalt. This operation was repeated for five layers, the outside layer, however, being of six-ounce saturated duck fabric, and the outside surface of this finally mopped with the waterproofing asphalt. Immediately following this, a 4-in. brick facing was constructed from the floor to the top of the wall, great care being taken to obtain a one-half-inch mortar course between the outside asphalt course and the inside face of the brick work. All of this work was started at the bottom and built up for the entire inside circumference of the wall in 6-ft. sections.

The work was started Nov. 20 in spite of the inclement weather and was completed and the reservoir refilled on Dec. 23. As the stagings on the side of the

wall were taken down, the whole inside face of the brickwork was thoroughly cleaned by washing.

Simpson Brothers of Boston were the general contractors on the work, W. A. Murtfeldt Co. of Boston, sub-contractor on the waterproofing, and M. F. Stankard of Waltham, sub-contractor on the brick work. The engineer's estimate on the whole of this work was \$16,500, while the low bid of the contractor was \$16,543.

Concrete Parking Strips on Asphalt Streets

CONCRETE side strips on widened gutters are being employed at St. Louis, Mo., in pavement reconstruction on streets where asphalt or other bituminous surfacing is adopted. These strips are 6 ft. wide and permit an automobile to be parked parallel to the curb and entirely clear of the bituminous roadway. It has been found on asphalt streets that the parts next to the curbs, due to the hindrance of parked cars, do not get the traffic needed to keep them ironed down in the best

CONCRETE PARKING STRIPS FOR BITUMINOUS PAVEMENT

condition. Also the traffic traveling a narrow center lane intensifies the danger of rutting and shoving. With the concrete parking strips, the full width of asphalt is clear for traffic and the distribution of traffic is reasonably uniform. Standing water is kept pretty well off the bituminous surface. The construction of the side strips corresponds closely to the regular city requirements for concrete curb and gutter.

The design is shown by the illustrations from an improvement on Russell Ave. A detail to be noticed is the use, where it was a part of the old pavement, of the Telford base as a sub-base for the new pavement. By carefully cleaning the surface of the old Telford a very satisfactory bond of the new concrete base and the stone sub-base is secured. W. W. Horner is engineer of the Board of Public Service of St. Louis.

Accelerations in Airplane Maneuvering

Measurements of the accelerations of an airplane in various complex maneuvers, recently made at Langley Field by F. H. Norton and T. Carroll for the National Advisory Committee for Aeronautics, are summarized in Report 163 of the committee. The plane used was of SE5A type; a three-component accelerometer and a recording air-speed meter were used. The maneuvers were a loop, a spin, a roll, a right and left wing-over turn, a side slip and a skid. The maximum normal acceleration (vertical for plane in usual position) was 3.80 times the acceleration of gravity, and occurred in a loop. The greatest lateral accelerations occurred in a spin and a side slip, reaching 0.35 and 0.40 times the acceleration of gravity respectively. The greatest longitudinal accelerations were 0.50 in a loop and a roll, and 0.60 in a wing-over.

Earth Moving Methods and Costs, Bronx Parkway

Record of Dragline, Steam Shovel and Heavy
Tractor Operations Covering Four Years
of Miscellaneous Earth Moving

BY GILMORE D. CLARKE

Superintendent of Construction, Bronx Parkway Commission,
New York

APPROXIMATELY 1,500,000 cu.yd. of earth moving, with a variety of machines, has been accomplished largely during the last four years in building the Bronx River Parkway north from New York City. Construction by force account made close cost records possible and the variety of operations and the special character of the work give these records exceptional interest. They represent a quite different situation than exists in normal drainage ditching and railway grading operations.

The lands in the Bronx River valley were acquired by the Bronx Parkway Commission, first for the purpose

WALKING DRAGLINE WIDENING RIVER CHANNEL
INTO A LAKE

of preventing the pollution of the Bronx River, which before public ownership was virtually an open sewer, and second as the route for a parkway connecting the New York city park system with the watershed lands in upper Westchester County. The reservation is approximately 16 miles long and varies in width from 200 to 1,200 ft., terminating at the Kensico Dam. Work

was begun in 1916 and continued until the war, little being accomplished during 1918. Operations were resumed in the summer of 1919 and during 1920, 1921 and 1922, general grading work was brought very nearly to completion.

Outline of Operations—The engineer's studies showed that it was necessary to lower the water level of the river throughout a greater part of its length in order to build a drive which would require a minimum amount of fill to bring it at all times of the year above flood level. To obtain enough material to bring the driveway to subgrade, and to grade adjacent areas to conform to proper landscape treatment, it became necessary in places to build lakes by means of which a large amount of fill was obtained. Most of the material for the drive and adjacent grading was taken from river and lake excavation and inasmuch as wet material was to be handled, machinery adapted for that particular kind of work was obtained. Conditions in the valley were at most times unfavorable for the type of machinery used by contractors in this part of the country and after canvassing the situation thoroughly it was decided that the work could be most economically prosecuted by force account.

The parkway parallels a line of the New York Central R.R. and in many places the river is close to the railroad embankment. Where this was the case the river was moved away to permit trees and shrubs to be planted to screen out the railroad right-of-way. The old river varied in width up to 30 ft.; the new channel was made 40-ft. wide at the lower end, narrowing to about 20 ft. toward the upper end near the Kensico Dam.

Dragline Performance—In 1917 a walking dragline excavator was purchased. This machine was adapted for excavation from below water level and was capable of standing upon rather soft marshy ground. It was equipped with a 40-ft. boom, a 1-cu.yd. bucket, a 45-hp. gasoline engine and a device for "walking" which it was believed would make it possible to work where no other excavating machine could work. It had a circular base about 12 ft. in diameter and when ready to move, two large pads, one on each side, were lowered to the ground and by means of revolving cams the machine was raised, took a step of about 4 ft., and assumed working position again. This outfit had its limitations, however. The gasoline engine caused constant vibration and when standing upon soft ground, the machine gradu-

DRAGLINE ON CRAWLER TRACTION DEEPENING RIVER

ally worked itself into the mud, and if operated in such a position the weight of the bucket and load often caused one side to settle. When this occurred, the cams were brought too low to engage the pads and the machine was unable to "step." Then quantities of brush or heavy plank were used on the soft places to provide a bearing.

Excellent service was given by this dragline, it having excavated, rehandled, and loaded in five years (Table 1) 317,397 cu.yd. at a cost of \$67,494.76, or a cost per cubic yard of \$0.21. This included the cost of the machine, fuel, oil, repairs, overhauling, operators, and two helpers necessary for each shift. When one considers that there is from one to three months' shut-down in winter; that, during the spring, work proceeds slowly on account of the condition of the ground, and further the unavoidable delay of loading teams through a hopper, this cost seems very favorable. The given yardage is computed from the bucket loads, not from yardage in place.

Early in 1920 a larger walking dragline was purchased as one of the sections to be developed in New York City and which the commission desired to complete in one year, required that approximately 140,000 cu.yd. of material be moved. Also there were no trees in the section to interfere with the operation of a large machine. The specifications were: Weight, 80 tons; boom length, 60 ft.; power, one 70-hp. Charter engine, single horizontal cylinder; fuel, kerosene; traction, the same as for the small dragline previously described, and bucket, 2 cu.yd. This machine was placed on two eight-hour shifts and in eight months during 1920 it excavated and rehandled 149,562 cu.yd., which cost \$20,105.56, or \$0.135 per cubic yard.

Steam Shovel Operation—Until the fall of 1919 no shovels for loading had been purchased and the dragline loaded teams through a hopper. This process was uneconomical; it was difficult to move the hopper and the output of the dragline was cut down due to the delay of the teams. It was also found impossible to load wet material excavated directly from river and lake and placed into the hopper and the dragline therefore rehandled material previously excavated and spoiled in piles, this material having had a chance to dry.

Realizing the necessity of a more economical means for loading teams, a revolving shovel, equipped with a 2-cu.yd. bucket and with caterpillar traction, was pur-

chased. This machine worked three years and during the time loaded 155,661 cu.yd. for a total cost of \$36,370.13, or \$0.233 per cubic yard. This machine has also been used in the construction of dry rubble retaining walls and when engaged on such work the shovel boom was removed and replaced with a 30-ft. lattice boom.

Supplementing the work of the 2-cu.yd. walking dragline were two revolving shovels with 1-cu.yd. buckets, used to load teams or trailers drawn by tractors, for the final placement of the excavated material. These shovels, together with another shovel of a similar type and two small draglines, were received from the Bureau of Public Roads, being engineer equipment declared surplus by the War Department in 1919 and made available to the states for road construction work.

During a period of 7 months in 1920 the two shovels, working with the 2-cu.yd. dragline, loaded 93,761 cu.yd. of material from spoil piles made by dragline. The total cost of operation, depreciation, fuel, etc. was \$14,497.27, the cost per cubic yard to load being \$0.154.

Tractor Haulage Operations—As operations moved north through the reservation, hauls became longer, much too long to use teams economically. Motor trucks could not be used on account of the soft ground and the nature of the material to be hauled. In some places the best kind of sand and gravel for road fill were found

TRACTOR TRAINS HAULING SPOIL TO FILLS

and in other places a heavy blue clay, which when compacted was impervious to water. This clay was used to build the long flat slopes from the driveway to meet the existing grade, and the sand was saved for road fill.

The long-haul problem was solved when in the spring of 1920, eight 10-ton artillery tractors were received from the government. These machines were new and were placed in service immediately. Fifteen 11-cu.yd. bottom-dump wagons were arranged into five trains of three wagons each and each wagon was loaded to full capacity and hauled by tractor. These tractors are ordinarily capable of hauling four trailers, but due to the heavy drag through wet clay three were all the tractors could haul economically. The following year, 1921, when hauling conditions were more favorable due to better ground, four trailers were used.

During two seasons' work seven 10-ton tractors hauled a total of 130,573 cu.yd., the total cost of operation being \$46,456.12 and the cost per yard \$0.355. The operating cost includes winter overhauling, a total expenditure

for parts and supplies of \$8,523.86 and overhead charges of eight per cent. Seven tractors travelled a total of 13,771 miles and required a total of 42,380 gal. of gasoline, giving a total of 3.07 miles per gallon of gasoline. The average cost of gasoline over two seasons was \$0.246. The cost per mile to operate the tractors was \$3.37. Spare parts and supplies made up about one-sixth of the operating cost.

The high cost of spare parts was due partly to the fact that the workmanship and materials on war made machines were inferior to those in the product on the market today, and due also to the high prices charged for spare parts. The tractors were subjected to hard usage, however, and hauled material through soft clay where no other vehicle could operate. Teams would have been out of the question in places where tractors operated successfully. In places where the ground was

General Summary—In a period of six years over 1,500,000 cu.yd. of material were excavated, rehandled, or loaded, in the construction work on the Bronx Parkway Reservation. The tables herewith show the number of cubic yards each machine handled, the total cost, and the unit cost. It will be noted that the average unit cost for shovel and dragline excavation is the same, 18½c.

The yardage does not represent the number of cubic yards measured in place, but a count of buckets of each machine given daily by each operator who was supplied with a counter for the purpose. The total yardage thus obtained was reduced by 10 per cent, the result being accurate enough for purposes of comparing the performance of one machine with another.

In considering the unit costs it should be kept in mind that in landscape development a certain amount of fussy work is necessary which adds materially to the

particularly soft, limbs of trees were placed across the tractor as a sort of corduroy, thus enabling the machines to keep on the surface and providing better traction. Often when the trailers sank deep into the mud it became necessary to uncouple the tractor and have it pull the trailers out by means of a cable 30 ft. or more in length. By this means, the tractor was often able to pull on ground giving better traction and was prevented from grinding itself deeper into the mud. For long hauls, those over $\frac{1}{4}$ mile, the tractor has proven the most economical method for hauling large quantities to fill.

Small Dragline Performance—The two steam draglines which were received from the government were equipped with 45-ft. booms and $\frac{3}{4}$ -cu.yd. buckets and were suitable for the work of widening and deepening the river channel, stripping topsoil, and lake excavation. These machines have small cabs and are more suitable for work around trees where working space is limited.

Due to the swampy nature of the ground over which one of these machines was required to travel a set of six pontoons was built, each being 4 ft. 8 in. x 6 ft., of 3x8-in. oak plank spiked together and having a cable loop in the center to make handling easy. With these pontoons these draglines were capable of excavating through soft undrained swamp where it was thought no excavating machine could travel until the swamp was drained. These two draglines have excavated and rehandled a total of 233,211 cu.yd. in two years at a total cost of \$45,895.49, the unit cost being \$0.196.

cost. It is necessary to strip topsoil before cuts and fills are made and pile it in storage piles to be saved for replacement after subgrading work is done. Shallow cuts and fills are necessary and trees must be preserved.

The reader must take these facts into consideration before comparing the costs presented herewith with the costs for drainage ditch work, railroad cuts and fills and other heavy grading of a similar nature. Naturally the costs on these projects of a purely engineering nature are considerably lower. Altogether, however, the results show that the commission was amply justified in its decision to accomplish the large amount of grading work by force account rather than by contract.

The Bronx Parkway Commission consists of Madison Grant, W. W. Niles and Frank H. Bethell. Jay Downer is chief engineer and L. G. Holleran the deputy chief engineer.

Forestry on New England Water-Works Lands

Reforestation of lands owned to protect public water supplies in five of the six New England states (Rhode Island not included) covers 12,220 acres and 15,261 acres more are available for planting. The total area of water-works lands owned by the eighty-odd works reporting the foregoing figures is 98,020. Details are given in paper by Philip W. Ayres, forester of the Society for the Protection of New Hampshire Forests in the *Journal* of the New England Water Works Association for June.

Federal Valuation of Railroads in the United States

Railroad Engineers Must Keep Valuation Records Up to Date—Value Affects Various Phases of the Railroad Problem

By EDWIN F. WENDT
Consulting Engineer, Washington, D. C.

Abstract of a paper presented at the Annual Convention of the American Society of Civil Engineers, at Chicago, July 11-12.

The success of federal regulation of railroads will depend in large measure upon the valuation of the properties engaged in the service of the public. The Valuation Act, Section 19a of the Interstate Commerce Act, approved March 1, 1913, provides that: "The commission shall investigate, ascertain and report the value of all the property owned or used by every common carrier subject to the provisions of this act."

Engineering Board—The commission promptly within the sixty days prescribed, organized a Bureau of Valuation in charge of a director. The engineering board, appointed May 1, 1913, consisted of five members, and the United States was divided into five districts: Eastern, Central, Southern, Western and Pacific, each including approximately 50,000 miles of railroads. This board held its first meeting on May 6, 1913, and the last on Sept. 22, 1920. Each district had a technical staff including a civil engineer in charge of roadway and track; bridge engineer in charge of structures; architect in charge of buildings; mechanical engineer in charge of locomotives, cars and shop machinery; electrical engineer in charge of power plants and electric traction; signal engineer in charge of signals and interlocking plants; telegraph and telephone engineer in charge of telegraph and telephone work. There was also a complete office organization for the assembling of all the data into final engineering reports.

The engineering board during its existence of 8½ years to Oct. 31, 1921, supervised the work of inventorying the entire 250,000 miles of railroads in the United States. This work was done in great detail. The length of every road, including the various main tracks, spurs and sidings, was measured by engineering corps. All excavations and embankments were cross-sectioned and computed. Bridges, buildings, signals, water stations, fuel stations, shops, roundhouses, turntables, cars, locomotives, shop machinery, signals, interlockers, telegraphs, telephones, gas plants, power plants, and all appliances of every kind and description were inspected, measured, enumerated and computed in accordance with the standard practices of the engineering profession.

The field work of making the inventory measurements, and the office work in connection with the computations, collections and assembly of the quantities of the different classes of property was done with such care and thoroughness that both the carriers and the public have been well satisfied with the results of the work. Great care was exercised in the preparation of the instructions which regulated the work of the field engineers. The maximum force of engineers, accountants and land appraisers engaged at one time on this work was 1,500, and the engineering profession may well feel proud of the accomplishment of the great task of collecting the fundamental data required by the Valuation Act.

Date Basis of Prices—Having completed the essential engineering data, the commission proceeded to price the engineering works on the basis of prices as of June 30, 1914. The selection of this date was in some respects accidental, since the valuation forces were assembled in 1913-1914, the World War had not begun, and it was thought that the economic level of prices at that time would constitute a fairly stable basis upon which to determine the value of railway property so far as rate making was concerned. But the war radically changed the situation and even after five years of peace the economic level of wholesale prices is 60

per cent above that of 1914. The Supreme Court has pointed out in the Southwestern Bell Telephone Case, 1923, that proper weight should be given to present prices.

Final Value—The Interstate Commerce Commission has issued a large number of tentative final valuations, and the valuation work has reached a stage where it is possible to precast the relation of final value to the investment accounts. Obviously the present value of some carriers is higher and of other carriers lower, than the investment account. However, speaking generally, it is highly probable that the aggregate values of the railroads, as found by the Interstate Commerce Commission, will substantially equal the capitalization. The commission in 1920 held that the tentative final aggregate value of the steam railroads is \$18,900,000,000, and this value, which is the rate-making value, is very close to the investment shown on the books. When the final aggregate value of all property of the railroads has been determined, the prospects are that the "present value" will be substantially the present total capitalization.

This being the case: What will be the effect of federal regulation upon the future development of railroad? The commission controls the issuing of future railroad securities, the regulation of car supply and distribution, the joint use of terminals, the construction of new lines and the abandonment of old lines. The commission is required to prescribe rates so as to enable the carriers to earn an aggregate annual net railway operating income equal to a fair return on the aggregate value of the railway property used in transportation. The commission decided in 1922 that 5½ per cent is a fair return. Thus the value of the property is fundamental, whether the question is a schedule of rates, capitalization, consolidation, depreciation, recapture of excess railway operating income, joint use of terminals, construction of new lines or division of joint rates.

Future Valuation Work—All regulation is to be based upon a consideration of the property, its nature, classification extent, use and value. The railways will find it necessary to maintain adequate technical staffs for constantly studying the value of the property in its relation to the above items and other phases of the regulatory problem. It will be necessary for them to do more work in the line of scientific research, and to submit the data to the commission. Thus there is a large field of usefulness for the engineer, accountant, statistician and economist.

The effect of future regulation will depend, in large measure, upon the thoroughness of the study of the various phases of the railway problem. The commission is obliged by law to predicate its decision upon the record developed at hearings, but the Transportation Act places such a great burden upon the commission that it will not be possible for its forces promptly to prepare the data needed. Therefore it will be necessary for the railways to furnish information essential for proper decision in the various issues which will grow out of the interpretation and enforcement of the Transportation Act. These issues involve the prosperity of one of the three greatest industries in America, the railway business with a capitalization of \$20,000,000,000.

The public interest requires a reasonable regulation of the transportation business, and the people are well satisfied with private ownership of railways under public regulation.

Rural Whole-Time Health Officer Service

Of a rural population of 51,496,017 in the United States, 5,957,616 or 11.58 per cent have the services of whole-time health officers, according to figures given in a paper by Dr. W. F. Draper, assistant surgeon general, U. S. P. H. S., in *The American Journal of Public Health* for June. Nineteen states have no such officers, including New York, New Jersey, Michigan and Minnesota. Vermont has 100 per cent, Ohio has 53.37 per cent, North Carolina has 39.75 and Alabama 36.50 per cent of its rural population under the care of whole-time health officers.

St. Louis Tests Three Water-Main Joint Materials

Cement and Leadite Superior to Lead for Resistance and Deflection, While Lead and Leadite Are More Readily Worked

BY LELAND CHIVVIS

Engineer-in-Charge, Distribution Section, Water Division,
St. Louis, Mo.

WATER-WORKS engineers have, in general, attacked the problem of electrolysis by devising either methods of preventing the return current from leaving the circuit over which it is intended to travel, or means by which the return current, once it had leaped to the pipe line, could be induced to leave it in an orderly manner at the end of its journey. In the first class are such devices as welded rail joints and insulated negative returns, and the effort to keep the potential gradient as low as possible by restricting the area supplied by any one power station. In the second class is the familiar expedient of bonding the pipes to the rail or direct to the negative bus bar. Most of us have neglected the obvious course of discouraging current flow on our pipes by making them as near non-conducting as the available materials will permit. We have continued to use a material in the joints which is a better electrical conductor than the cast iron itself when there were available a number of other jointing materials which are very fair insulators.

The purpose of this paper is to describe tests made by the St. Louis Water Division to show the comparative electrical resistance of lead, cement and leadite in a bell-and-spigot joint and to determine their ability to withstand deflection. Three 50-ft. lines of 3-in. pipe were laid on supports and capped at the ends. Corporation cocks were inserted for filling and draining. One line was jointed with lead, a second with leadite and after waiting a month for weather suitable to making cement joints, the three lines were brought indoors as shown by the accompanying sketch. The cement joints were made by driving in two strands of regular oiled jute filling with stiff neat cement and ramming this home with a follower of a third strand of jute, finishing with the jute flush with the bell. A beveled collar of neat cement was added partly for appearance and partly to aid in permeating the third jute ring. The lead and leadite joints were made according to standard practice.

After about two weeks' time a six-volt automobile battery was coupled up with a resistance, a voltmeter and an ammeter (see sketch), contact points were filed on each side of the joints, the pipes were filled with water and the tests shown by the table were made.

The resistance of the pipe body between the joints is negligible as it is equivalent to a copper cable $\frac{3}{8}$ -in. in diameter. It will be noted that some of the overall resistances (joints 1 to 4 inclusive) do not check the sum of joints 1, 2, 3 and 4 taken individually under the same conditions. This can only be explained by assuming faulty contacts where the resistances seem unduly high. If work of this kind is ever attempted again we intend to drill and tap the pipe and solder all wires. The results show that on a leadite or cement line most joints have 500 or 600 times the resistance of a standard lead joint.

After the electrical tests were completed the lines were again put under pressure and some very severe deflection tests were made by alternately hoisting and lowering at the mid-section and again at one end.

The cement and leadite joints stood this treatment very well, the leakage being practically nothing although the visible part of the jointing material cracked and even spalled off in the case of the cement. Lead joints 2 and 3 leaked badly and had to be recaked before the test had gone very far. Joint 3 finally squeezed out of the bell about an inch and would have blown out if the

ELECTRIC-RESISTANCE AND DEFLECTION TESTS ON CEMENT, LEADITE AND LEAD JOINTS IN CAST-IRON PIPE

Three parallel lines of 3-in. pipe, each 50 ft. long, with electric contact points, as shown in the sketch immediately below, were tested (1) with the pipes full, under pressure, and then (2) with pipes empty but otherwise under same conditions as (1). The results of (1) indicate that the water conducts very little current around the joints.

volume of water behind it had been anything larger than the capacity of the $\frac{3}{8}$ -in. hose used for filling.

The lines were now leveled on supports and time taken for the removal of the jointing material. The six lead joints were burned out by one man with an oxy-acetylene flame in $\frac{1}{2}$ hr.; the leadite was burned out by the same man in 1 hr., the increase in time being due to the sulphur fumes. The six cement joints were gouged out by two men in $3\frac{1}{2}$ hr. of very tedious work.

A summary of the results follows:

1. **Cement and Leadite** are far superior to lead as insulators. The insulating value of these materials is not vitiated by the water in the pipe.

2. **Cement and Leadite** will stand far more deflection than lead without serious leakage.

3. *Lead and Leadite Joints* can be made in any season and under adverse conditions, while cement is under a disadvantage in winter and in wet trenches.

4. *Lead and Leadite Joints* permit the water to be turned on and the line put in service immediately, while cement requires a period of preliminary setting.

5. *Cement Joints* are very hard to gouge out.

CEMENT, LEAD- AND LEADITE-JOINTED 3-IN. CAST-IRON PIPE UNDER DEFLECTION TEST

6. *The Sulphur Fumes of Leadite* might become very oppressive in a confined working space.

These tests were made by men thoroughly conversant with the use of lead who were staunch in its support until the rising price made the substitutes look attractive. St. Louis is now preparing to lay a considerable amount of small pipe with cement joints and if lead does not drop appreciably before winter we will probably try leadite during the freezing weather.

Cantilever Bridge of Concrete

Monolithic Structures Supported on Piers—Heavy Abutments Not Required—Clear Channel Span of 51 Ft.

By PAUL M. HENRY

Bridge Engineer, Ohio State Highway Department

IN CONNECTION with the improvement of the Newark-Mt. Vernon intercounty highway in Ohio, two reinforced-concrete bridges of an interesting design have been built. One is over the Lake Fork and the

other over the Lake Fork, in Licking County. Both bridges are of the reinforced-concrete cantilever type of 54-ft. span, the only difference in them being in the height of their piers.

The bridges were designed to carry a 15-ton truck. The floor-beams carry the floor and load and transfer it to the girders at the floor-beam points as concentrated loads. Influence lines were used to determine loadings for maximum stresses. To avoid the use of construction joints in the main structure the floor and two main girders of each bridge were poured in one

CANTILEVER CONCRETE BRIDGE FOR OHIO HIGHWAYS

operation. The approach slabs at each end of the structures were poured later. The top of the floor-beam at each end of the cantilever was provided with a half-round groove 4 in. deep, for the entire width of the roadway, to support the approach slab. This groove was painted with a coat of bituminous material before the slab was poured. The design called for the outer end of this slab to rest on the fill, but in construction it was provided with a shallow foundation 3 ft. deep and 1½ ft. thick.

The Newark Paving & Construction Co. which had the contract for the entire improvement, both road and bridges, sublet the bridges to B. C. Patterson at approximately \$13,000 each.

ELEVATION AND CROSS-SECTION OF CONCRETE CANTILEVER BRIDGE AT LAKE FORK, LICKING CO., OHIO

Undiscovered Substratum of Peat Complicates Foundation Job

Shallow Foundations Settle During Construction—
Original Borings Inaccurate—Unusual
Method of Underpinning

SETTLEMENT of the foundation during the construction of a ten-story building due to the use of inaccurate borings which presumed to indicate the character of the material underlying the site, has forced the builders to resort to an unusual method of underpinning the foundation of the Westinghouse Electric & Manufacturing Co. building in Philadelphia. At the time the property was purchased by the present owners they received from the former owners a series of borings which indicated that a loose fill 8 to 10 ft. deep and a uniform bed of clay and sand was all that overlay the rock, which was about 45 ft. below the surface. These borings were accepted by them as being accurate and a shallow pile foundation was put in.

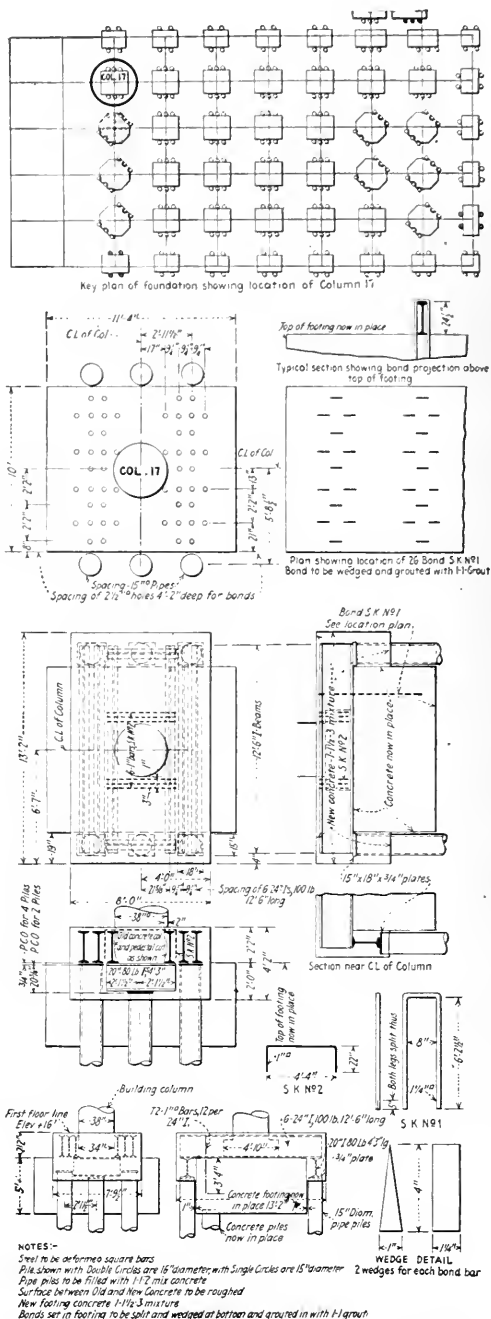

When construction work was started the Raymond Concrete Pile Co., subcontractors under the Hughes-Foulkrod Co., drove test rods to determine the length of piles required. The test rods were driven to a depth of from 25 to 30 ft. at which depth the penetration of the test rods indicated that piles would sustain the contemplated loading. When the actual piles were driven, their length and resistance closely agreed with what was to be expected from the driving of the test rods and the boring records.

The driving of the piles for the footings was completed and eight of the stories of the building had been erected when a considerable settlement over a large part of the foundation area was noted. The building construction was immediately stopped and core borings were taken. These borings showed that, except under the two rows of footings at the west side of the building, the first 25 to 30 ft. of material was about as indicated in the original boring record, but that underlying this layer of clay and sand was a very compressible layer of peat and silt. Under these circumstances each individual pile developed sufficient resistance to carry its assumed loading, but when the weight of the building was put upon all of them it developed compression in the stratum of peat which resulted in a settlement varying from about 4 in. at the east side of the building to nothing at the west side. The piles at the west side where there was no substratum of peat carried their load without settlement.

In order to further verify the result of these core borings, the contractors had an open-end reinforced-concrete caisson with an inside diameter of 4 ft. sunk to bedrock and completely excavated. The excavation disclosed the following layers of sub-soil:

- 27 ft. of fill
- 4 ft. of peat
- 1 ft. of gravel
- 15 ft. of silted peat
- 8 ft. of silt
- 2 ft. of coarse sand and gravel on top of very hard mica schist

In the meantime, in order to avoid undue settlement during the underpinning operations, each column was shored up. It was necessary to take the shores up several times a day to compensate for the continuous compression of the soil on which they bore.

FOUNDATION PLAN AND DETAILS OF ONE FOOTING
Showing location of the new piles in relation to the original
footings and method of transferring the load to them.

The method of underpinning the foundation is shown in the accompanying drawing. Each footing is supported on a group of 15-in. or 16-in. concrete filled steel pipe driven to rock outside the original footing. These pipes were sunk without removing any of the floors of the building which had already been placed. When each pipe had been firmly bedded on the rock it was cleaned out with compressed air blown through a 2½-in. nozzle at 110 lb. pressure, sealed with neat cement, and con-

SETTLING FOUNDATION CARRIED BY CROSS BEAMS

creted up to the cutoff elevation. These pipes were then capped with short steel I-beams. Steel beams with their outer ends resting on these caps were placed across the top of the original footings. The footings were then suspended from these overlying girders by means of 1½-in. deformed U-bars which were split and wedged at the bottom and securely grouted in place. After this concrete had been allowed to set for ten days steel wedges and shims were placed between the U-bolts and the I-beams, and between the caps and the top of the concrete-filled pipes. The whole footing was then completely encased in concrete.

The underpinning described was designed and executed by the Raymond Concrete Pile Co., following the requirements of the Philadelphia building department. Percival M. Sax acted as consulting engineer to the contractors. Application has been made for patents on this method of construction.

Engineering Charges on Local Improvement Work

A bill permitting municipalities to include engineering and inspection as items in the cost of local improvement work has been passed by the Illinois state Legislature, largely through the efforts of the Illinois Society of Engineers. No percentage is fixed by the law, but this is left to the decision of the municipalities. According to a statement in the 1923 *Proceedings* of the society this bill was the outcome of a decision by the Illinois Supreme Court in 1922 to the effect that engineering and inspection during the construction of improvements by special assessment are not a part of the cost of the work. This decision operated to the disadvantage of many improvements in the smaller municipalities, few such municipalities having corporate funds out of which to pay these expenses. It operated also to the serious disadvantage of engineers for such work. Since nothing more could be accomplished through the courts, the next step was to get the legislature to amend the statute so as to provide specially for these items, and this has now been done.

Truss Supports for Cantilevers of Theater Balconies

IN THE structural design of large modern theater buildings a typical feature is the introduction of long steel trusses as fulcrum bearings for inclined concrete girders supporting the balcony floor. This arrangement eliminates intermediate columns in the main floor and provides an unobstructed view. Difficulties in location and design of the trusses are encountered, especially the difficulty of combining long span and shallow depth in the steel trusses, a condition involving heavy members.

Three different arrangements of balcony trusses are shown in the accompanying drawing. Plan No. 1 shows the simplest arrangement, as used in the Keith Theater at Euclid Ave. and 17th St., Cleveland, the anchor span single steel truss, A, of 87-ft. span, supported on interior columns, carries the six inclined concrete girders, B, which have a maximum cantilever length of 33 ft. and an anchor span of about 34 ft. Owing to the limited

TRUSS AND CANTELEVER FRAMING OF BALCONIES

depth of truss the necessary amount of material for the required strength is obtained by using a twin truss, with parallel double chords and web members.

In plan No. 2, which represents the Palace Theater at Euclid Ave. and 17th St., Cleveland, the anchor span of the concrete girders, B, is about 46 ft., while the maximum projection beyond the truss, A, is about 44 ft. Since this distance would be excessive for a cantilever, two diagonal trusses CC, are introduced, having their inner ends framed into the main truss, A, and their outer ends supported by side columns. Owing to the interior arrangement these diagonal girders are not symmetrical, one being 39 ft. and the other 49 ft. long. In this way the cantilever lengths of girders B are only from 27 to 30 ft. This theater construction was described in *Engineering News-Record*, June 22, 1922, p. 1036, and the truss arrangement is like that of the State-Lake Theater, Chicago (see July 24, 1919, p. 178.)

A more complicated arrangement was required to meet the conditions of architectural design in the Chicago Theater, Chicago, as shown in plan No. 3. In this case columns could not be placed at suitable points for supporting the truss A. Two 76-ft. diagonal trusses, C, were therefore placed on side columns, and the 88-ft. truss, A, was framed between them. This is a twin truss, similar to that in plan No. 1, but a more effective distribution of metal is effected by the use of an H-section for each of the four chords, thus permitting the use of as many vertical cover plates as desired.

The architects for the three theaters were C. W. and George L. Rapp, Chicago, and the structural designs were by Lieberman & Hein, engineers, Chicago.

Letters to the Editor

This department aims to be a forum for the discussion of the views of engineers and contractors. The range of interest should be as wide as possible. Contributors are, therefore, asked to make their letters short.

Trial of Acid in Dewatering Imhoff-Tank Sludge at Plainfield, N. J.

Sir—Experiments on sludge dewatering with sulphur dioxide gas were mentioned by J. R. Downes, superintendent, Plainfield sewage-works, in your issue of July 5, p. 29. The sulphur dioxide conditioning process is controlled by this company and has been in successful operation on activated sludge for some time at the Houston, Texas, and Gastonia, N. C., plants.

The process was installed experimentally at a small sedimentation plant in the Borough of Brooklyn, New York City, and produced favorable indications. This plant was moved to the Plainfield, N. J., sewage-works in the late fall of 1922 with the understanding that one of the Imhoff tanks would be cleaned out for the purpose of delivering an undigested sludge to the experimental dewatering plant. Due to lack of sludge bed facilities, the Plainfield people were unable to clean out a tank and deliver fresh sludge, so we were compelled to attempt to handle digested Imhoff sludge with a high proportion of colloidal solids. Despite the fact that the particular machine set up at Plainfield was not designed to handle this type of sludge, fairly good indications were developed, although the experiments had to be discontinued before any conclusive data could be collected, due to cold weather with attendant difficulties.

This company has issued no data on results produced with any other sludge than activated, but feels that this brief statement covering the Plainfield experiment should be forthcoming in view of the possibly misleading communication from Mr. Downes.

New York City,
July 10.

R. H. EAGLES,
Sanitary Engineer, MacLachlan
Reduction Process Co., Inc.

State Highways in Small Towns

Sir—I disagree with the editorial entitled "Off Into The Mud" in the June 14 issue of *Engineering News-Record*, in which you state that the small towns in the Northeastern states are conspicuous for their poor pavements, and that these pavements should be brought up to the standard of the state highways.

I am a resident of one of the small towns in question, in which the pavements are generally in the condition you refer to, particularly on the street where I live, which, although a side street as far as the town is concerned, is now a connecting link in the state highway system. A few years before the highway was built this street was paved with a waterbound macadam and of recent years it has been frequently oiled to keep it in shape.

Under normal conditions this pavement would have served us for a good many years, but with the vast stream of automobile traffic, including large trucks of a number of apparently very prosperous concerns now in the business of handling freight over the state highways, the pavement of this street has been almost entirely broken down. Quite naturally we are not inclined to spend more money on rebuilding this street, particularly as the estimated life of the original pavement is not up yet, and bonds are still in existence. Also, from a selfish point of view, the present condition of the pavement insures a safe rate of speed for the passing automobiles, in a street where we have no money to provide traffic policemen, and consequently have to cross at the risk of our lives.

In view of all this I do not see why we should be called upon to repave this street for the benefit of this state and interstate traffic, and particularly for the benefit of the trucking concerns that are getting rich competing with the

railroads that have to maintain their own "running lines" as our British friends would say. It seems to me that it would be more fair to the people of the small town, who get little benefit from this traffic, if the state highway pavements were carried through such towns with only a small percentage of the cost assessed against them.

"ENGINEER."

Balanced Bids—Duty of the Engineer

Sir—I have read with interest and approval the letter from E. T. Thurston of San Francisco, in *Engineering News-Record*, July 5, regarding "Unbalanced Bids," and the reason therefor, and wish to concur with him in his statement urging the engineers and architects of the country to base all estimates on experience of such work as is being estimated.

If every engineer and architect would write his specifications with due regard to the actual operations necessary to perform the work, and make the plans for such work conform in every respect to the shape and finish of the completed work, he would not only save his client money but would make his own position more secure with both the owner and the contractor; for an honest and competent contractor will do better work and can do it for less money when the man in charge is just as experienced in the actual operations of the work to be performed as is the contractor himself, and there will be very little chance for differences to arise as to the interpretation of the specifications when they are written with both technical and practical knowledge.

To-day the majority of the contractors are, or have employed as their superintendents of construction, graduate engineers, so it behooves the engineer to wise himself up on the "way to do" as well as "how to do" every kind of work on which he proposes to write the specifications and supervise the construction.

As Mr. Thurston so aptly states, every engineer and architect who undertakes conscientiously to give his client the same degree of responsible service as he demands that the contractor give such client, must secure himself in the position to provide that contractor with as nearly perfect plans and specifications as is humanely possible.

Amarillo, Texas
July 16, 1923.

W. D. HOWREN,
Consulting Engineer.

Seek Apprentices in the Field Operations

Sir—Your editorial, "Who Restricts Apprentices," p. 45, issue of July 12, 1923, while exonerating the labor unions would have been more to the point if suggesting to the contractors to look for the fault in the field operations.

The writer, who for the past fifteen years has been connected with the largest contractors of Philadelphia and Washington, D. C., has never been discouraged either by the contractors or labor unions from trying out intelligent boys as apprentices.

Generally the plan followed when employing large or small forces of common laborers was to hire a few well developed boys as laborers and, if found industrious and capable of holding down a common laborer's position, after a few weeks they were allowed to try out as apprentices. This plan generally succeeded, for the boy had to have the grit to stand up under a constant fire of being hurried under a labor foreman which helped to weed out the laggard and find the boy who was fit to keep pace with the mechanics foremen.

Further the boy was allowed to assist in the engineering work that each operation required. If the boy was found exceptional he made the grade of foreman in a shorter time than the average slower mechanic, thus developing a supply of mechanics who could always make good when called upon to shoulder some of a field operations responsibility.

Personally I feel that a little propaganda at the field operations will produce more apprentices—as when boiled down to facts the boys are available—if the job superintendents would go a little out of their way to produce them and to oversee their progress.

THOMAS F. MACDEVITT,
Construction Superintendent,
Washington, D. C.

July 23, 1923.

News of the Week

CURRENT EVENTS IN THE CIVIL ENGINEERING AND CONTRACTING FIELDS

News Brevities

A survey of the New York elevated railways is to be made by George F. Swain, professor of civil engineering at Harvard University. This work has been authorized by the New Municipal Transit Bureau. Prof. Swain was chairman of the Boston Transit Commission for five years and is a past president of the A.S.C.E.

To Mark the Completion of the Alaska Ry., President Harding recently drove a gold spike at the Tanana Bridge. The citizens of Anchorage presented the spike to Col. Frederick Mears in appreciation of his work as builder of this 471-mile line between Seward and Fairbanks.

A New Traffic Ordinance for New Orleans has been compiled by Commissioner Ray of the Department of Public Safety and will be presented to the Commission Council for adoption. This new traffic code includes regulations needed by local conditions and those successfully tried out in other cities, and will relegate to the discard many antiquated ordinances.

The Indiana State Highway Department Must Have, according to John D. Williams, director, 10 more engineers, 20 more state road inspectors and 30 more county road inspectors on the construction of 235 miles of roads of which 170 miles will be hard surface, 35 miles of secondary type and 30 miles improved by grading and building structures. State inspection is in force on forty-one county projects, consisting of 125 miles of road improvements, to cost approximately \$2,254,000.

Authority to Construct 380 Miles of Railroad from Tucumcari, N. M., to Seymour, Tex., and from Perrin to Fort Worth, with a possible addition of 100 miles to the above has been asked of the Interstate Commerce Commission by the Texas, Panhandle & Gulf Ry. Co. The company has also applied for authority to buy or lease the tracks of the Gulf, Texas & Western R.R. Co. from Seymour to Salesville in Palo Pinto County.

An Application for a Rehearing in the assigned car case has been made to the Interstate Commerce Commission by the various subsidiaries of the U. S. Steel Corp. The petition points out that none of the coal mined by the applicant mining companies is sold in competition with coal mined in the same or adjacent districts, that the nature of the manufacturing process requires a continuous operation of a steel plant, and that the distance between the plants and their coke ovens on the one hand, and the mines on the other, requires the use of private cars to insure continuity of the coal supply.

Moffat Tunnel Bids Wanted

The Moffat Tunnel Commission will receive bids Aug. 25, 1923, for the excavation work on the main and pioneer tunnels for the Denver & Salt Lake R.R. under James Peak in Grand County, Colo. The tunnels will be 6.04 miles long and at 65-ft. centers. The main tunnel will be 16x24 ft. and the pioneer tunnel will be 8x8 ft. Cross headings between the tunnels are to be cut at as many points as the contractor finds desirable. The \$6,750,000 bond issue has been sold at a substantial premium, the contract for supplying electric power to the two portals has been let, and the installation of equipment is now in process. R. H. Keays is chief engineer, and V. A. Kaufman is resident engineer.

Bridge Design Dispute Initiated by Architects

Supplementing the statement published last week (p. 155) as to the controversy over the design of the three new Allegheny River bridges which are to be constructed in Pittsburgh, it is reported that the controversy originated with demands on the part of architects that the board of county commissioners turn over the design and supervision of the bridges to them. John W. Beatty, director emeritus of the Department of Fine Arts, Carnegie Institute, appeared before the board and made such a demand. Subsequently a committee of the Pittsburgh chapter of the American Institute of Architects came before the board to support the Beatty demand. As a result of this meeting the commissioners asked the committee to supply a list of the names of local architects competent to take charge of such bridge construction. The controversy incidentally has included such misleading statements as that an architect designed the Manhattan bridge over the East River at New York.

Penn State College to Train Industrial Executives

Pennsylvania State College, through its industrial engineering department, offers a special summer course of two weeks to industrial executives. For seven years, under the leadership of such engineers as Hugo Diemer, a group of industrial executives have met for two weeks at State College and through intensive study, lecture and laboratory work have gone into the field of costs, rate setting, personnel, planning and production with a view to training in executive co-ordination. Each year about twenty-five leading plants have been represented. This summer the course is given in the industrial engineering laboratory from Aug. 27 to Sept. 8. Information may be secured from J. O. Keller, Head, Industrial Engineering Dept., State College, Pa.

Bids Received for Steelwork on Philadelphia-Camden Bridge

Bids were opened by the Delaware River Bridge Joint Commission on July 18 for construction of the two inclined steel bents carrying the cable saddles at the anchorages of the Philadelphia-Camden suspension bridge. Two bids were received as follows:

	Steel Lbs.	Bethlehem Steel Co.	American Bridge Co.
Silicon Steel	2,030,000	9 1 c	9 3 c
Carbon steel	650,000	8 7 c	9 3 c
Cast steel	950,000	15 0 c.	11 7 c.
Steel supports for bents.	200,000	7 9 c.	8 1 c.
Total..		\$399,580	\$376,590

Although underbid on every item except that for cast steel, the American Bridge Co. was low bidder and its proposal was accepted by the commission.

The bents are inclined steel supports to hold the cables in position and to deflect them downward for their anchorage into the masonry. Each bent has two columns, 7 x 8 ft. in section, of cellular construction, braced together by diagonal and cross members, and carrying saddles in which the cables will rest. Saddles and column bases are cast steel. The columns are silicon steel, of the same grade as that being used in the main towers of the bridge, (yield point 45,000, ultimate strength 80,000 to 95,000, pounds per square inch). The column bases rest upon inclined surfaces of concrete at the river end of each anchorage. Bearing on the concrete will be effected by grouting. The total force to be carried by each bent, under maximum conditions, amounts to 48,400,000 lb.

The contract time for completion of the bents is nine months, but the contractor is required to have them in condition to permit stringing of the cables in eight months.

Federal Judge Rules City Cannot Extend State Traffic Law

Judge Robert S. Bean, U. S. District Court, sitting at Portland, Ore., has decided that a city or municipality has no right to add to or extend a state law on any subject. The opinion arose from a situation wherein A. F. Davidson, a motorcycle policeman, sued Walworth & Co. because of injuries suffered in a collision with an automobile owned by the defendant company. The policeman charged that he had the right-of-way because of an emergency while in the discharge of his duty. The state law lists certain vehicles and occupations which are given rights-of-way so far as traffic is concerned but motorcycles are not included in the state law. However, the city of Portland's ordinances do include motorcycles as well as other fire and police vehicles as having special traffic privileges.

The court decided that the complainant based his suit upon an extension of a state law and therefore the case was thrown out of court on a technicality.

Rapid-Transit Agreement in Philadelphia

City and Traction Company Work Out
Subway and Elevated System
Costing 60 Millions

After discussions extending over more than a year, agreement has virtually been reached on plans for rapid-transit development in Philadelphia. These plans are in effect changes in the Taylor Plan, adopted by the city in 1916. Work on certain portions of the subways included in that scheme had been started when increasing costs caused by war time conditions forced postponement of construction.

Recent discussions have centered principally upon the number of tracks to be constructed in Broad St., the terminal points for that line, and the disposition to be made of the loop subway for delivery of Broad St. subway traffic in the center of the city. Injected into the discussions has been the political feud between the mayor and the majority faction in city council.

The plans upon which agreement now seems likely provide for a comprehensive scheme of development, and for a first step in that scheme. A four-track subway is provided in Broad St. from Olney Ave. south to Spruce St., approximately eight miles, with a two-track subway extending south from Spruce St. to the Navy Yard at League Island. A two-track subway is provided in Ridge Ave., leading from the Broad St. line to Eighth St. and then by way of Walnut and Chestnut Sts. to a point in West Philadelphia near 42nd and Chestnut Sts., continuing from that point as an elevated line to the southwestern portion of the city and to Darby. A surface-car subway is provided in Chestnut St., in which it is proposed to run all surface cars now operating on Chestnut and Walnut Sts., thus leaving those streets free for motor traffic. This feature is one of great importance in view of present congested conditions on these streets. Subway lines are provided in Arch and Filbert Sts., with connections to the Delaware River bridge (under construction) to Camden, and with extensions as elevated

	Structure	Trackwork	Equipment	Cars	Total
4 Track Subway—Broad. Olney to Spruce	\$34,240,000	\$2,900,000	\$4,440,000	\$9,220,000	\$50,800,000
2 Track Subway—Ridge. Broad to Eighth	3,540,000	210,000	330,000	670,000	4,750,000
2 Track Subway—8th. Race to Walnut	2,580,000	110,000	160,000	350,000	3,200,000
2 Track Subway—Walnut, Chestnut 8th to 23d	6,110,000	310,000	480,000	1,000,000	7,900,000
2 Track Bridge and Approaches—Chestnut, 23d to 30th	1,400,000	60,000	90,000	200,000	1,750,000
2 Track Subway—Chestnut, 30th to 42d	3,960,000	280,000	410,000	850,000	5,500,000
2 Track Elevated—42d. Woodland, Chestnut to Darby	4,880,000	820,000	1,270,000	2,630,000	9,600,000
Totals	\$56,710,000	\$4,690,000	\$7,180,000	\$14,920,000	\$83,500,000
Terminal Yards and Shops					6,500,000
GRAND TOTAL					\$90,000,000

FIG. 1—PROPOSED FIRST STEP

City council special transit commission has indicated approval of this plan. Suggestions have been made for minor changes on the Darby line, one plan being for a continuation of subway construction in the 42nd St. portion from Chestnut St. to Woodland Ave., and another being for extending the Chestnut St. portion to 16th St. and then turning south to Woodland Ave.

railways to Overbrook and to Roxborough.

The first step in the plan, which is designed for immediate construction, comprises the Broad St. subway from Olney Ave. to Spruce St., together with the Ridge Ave., Eighth St. and Walnut

Chestnut St. subways, and the elevated railway to the southwest and Darby. The estimated cost of this portion of the work, as computed by engineers of the Philadelphia Rapid Transit Co., is given in the table.

This portion of the plan was incorporated in an ordinance which was passed by the city council at a special meeting held on July 27th. The ordinance also provides for the reappointment of the funds already voted for subway construction. The special session was held in order that there may be time to repass the measure, in case it is vetoed, in time to submit it to vote at the primary election in September.

The Philadelphia Rapid Transit Co. has offered to pay sinking fund and interest charges on the money required for the Chestnut St. surface car subway so that its construction will not encumber the borrowing capacity of the city. An ordinance covering the construction of this subway is being prepared for submission to the people at the general election in November.

The contract for the construction of 1529 ft. of two track subway in Arch St. between Eighth St. and Thirteenth St. was awarded on July 27th to the Keystone State Construction Co. for \$1,198,555. This section of subway under Arch St. is a portion of the "delivery loop" and is not included in the first step of the council's construction program.

New Orleans Zoning Ordinance Legal Says High State Court

The right of New Orleans to exclude business enterprises from residence districts through zoning was upheld by a unanimous decision of the seven judges of the Supreme Court of Louisiana in a decision handed down on July 11. Brief excerpts from the decision, given in the New Orleans Item of July 12, indicate that the court went so far as to hold that the exercise of the police power in zoning may be extended to esthetic considerations in so far as these include eyesores in residential districts that affect the comfort and happiness of the residents and the value of their property.

Port Authority Elects Officers

Eugenius H. Outerbridge has been re-elected chairman of the Port of New York Authority; DeWitt Van Buskirk as vice-chairman succeeds J. Spencer Smith, whose term as a commissioner expired on July 1. Julian A. Gregory has been appointed a commissioner, vice Mr. Smith. William Leary has been re-elected secretary, Julius H. Cohen, counsel and Gen. Geo. W. Goethals, consulting engineer.

FIG. 2—PROPOSED COMPREHENSIVE PLAN FOR PHILADELPHIA
TRANSIT DEVELOPMENT

This plan includes the following changes from the plans adopted by the city in 1916: (1) Inclusion of surface subway and high-speed connection to the Delaware River Bridge, which had not been started at the time the 1916 plans were developed; (2) abandonment of the plan for a "delivery loop" in the central section of the city as a terminal for the Broad St. line, and (3) the construction in its place of the Ridge Ave. line. This arrangement permits of through routing on all lines.

No Justification For Davis Dismissal Revealed

All Evidence Still Shows Reclamation Service Reorganization Due to Politics

Washington Correspondence

Nothing to justify the abrupt dismissal of A. P. Davis from his position as director of the Reclamation Service has developed since the Secretary of the Interior took that action. Such justification as has been proffered on his Alaskan trip by Secretary Work and by his assistants at Washington seems to have been refuted as the facts became available.

One of the reasons put forward for the summary character of Mr. Davis' dismissal was that the situation of the water users is so desperate as to make necessary drastic action. That the farmers on the reclamation projects are in any such plight as that described at Secretary Work's office, seems to be contradicted by the Secretary of Agriculture who is authority for the statement that "the financial distress among farmers on these projects is no greater than the financial distress of farmers not on reclamation projects throughout the region from the Missouri River west. In that region there are large sections in which I have no doubt agricultural distress is greater than on the reclamation projects."

As the situation is being analyzed more thoroughly, those who are looking into the matter are more convinced than ever that the motive behind the change was an endeavor to secure a partisan political advantage. During the entire time Arthur P. Davis was at the head of the Reclamation Service, he did all in his power to prevent attempts to dilute the reclamation fund. He feels that there are too many projects as it is, and that successes must be made of those before attempting to take on more. This policy aroused bitter complaint from those who are anxious to have Uncle Sam undertake further development. There is reason to believe that no small part of the influence which resulted in the ousting of Mr. Davis came from those who are anxious to interest the federal government in the Columbia Basin project. To this, however, must be added the influence of those who wanted to see Mr. Davis removed from the path along which their various schemes must advance, to say nothing of those concerned with existing projects who would repudiate obligations.

ACTION DOUBTLESS HASTY

Whenever a new secretary takes over the direction of the Interior Department, he is at once the target for hundreds of letters from those who are disgruntled and from those who want to depart from established policy. While these protests probably represent the opinion of only one-tenth of one per cent of those concerned, they do make an impressive pile when they converge on the desk of a new secretary.

Being inexperienced in the handling of large affairs and being a man with an explosive disposition, Secretary Work is thought to have rushed to a decision in regard to the conduct of the Reclamation Service, without consulting the very capable men in his department who are in a position to counsel him wisely.

All Acquitted of Conspiracy in Phillipsburg Sewage Case

All of the defendants in the charges for conspiracy to defraud the town of Phillipsburg, N. J., of some \$23,000 of extras for the construction of sewage works were acquitted by the trial jury of Warren County on July 26. The grand jury indictments were brought against the Municipal Disposal Co. (now the Direct Oxidation Disposal Corporation) of Philadelphia, contractors for the work, H. Jerome Hirst, president and Charles E. Parry, engineer, of the company; C. E. Tilton, town engineer of Phillipsburg while the work was under construction; and Edward and Francis Korp of the Korp & Korp Construction Co., of Phillipsburg, the last-named company being the subcontractor for part of the sewage-works.

The contract price for the entire plant was \$147,980, of which \$122,000 was for the machinery and equipment and \$25,980 for other material and labor. The Municipal Disposal Co. subcontracted with Korp & Korp for all the work outside the plant and machinery, the contract agreement being for cost plus 15 per cent. Mr. Tilton, as town engineer, certified to extras on the subcontract work totaling \$26,556 and his certification was approved by the town commissioners. The Grand Jury held that the greater part of the extras allowed should have been included in the contract price, but to this the trial jury did not agree.

The town commissioners were not indicted but four of the five commissioners (the fifth was not in office at the time the certificates were approved) were censured by the Grand Jury for disregard of state laws in letting contracts and in authorizing contract payment, and for various other sins of omission and commission — some of which, however, had nothing to do with the sewage-works contract.

Mr. Tilton is still under indictment for malfeasance in office. Further particulars regarding the original indictments may be found in *Engineering News-Record*, April 22, 1922, p. 710.

There is reason to believe that Secretary Work brought up at a cabinet meeting the need for changes in reclamation policy. The cabinet is thought to have agreed that something should be done, but the clumsy way in which the idea was carried out is not likely to meet with approval of the President or any of Dr. Work's ministerial associates.

Despite the fact that Mr. Davis was active in the effort to secure the transfer of river and harbor work from the Corps of Engineers, the consensus of opinion in that organization appears to be strongly condemnatory of political interference with the conduct of a technical bureau and of the sweeping indictment of the engineering profession in Secretary Work's announcement that the Reclamation Service should be in charge of a business man and not an engineer. Engineer officers point out, however, that this incident constitutes striking proof why river and harbor work should be left in their department. Since the army engineer can not be discharged, he is in a position to be entirely independent of political influence by the proponents of some project which he did not approve.

Contract Let on Indiana Stadium

Contract has been let for about half the reinforced-concrete stadium which will be built soon by the University of Indiana. The structure is of reinforced concrete with an ultimate seating capacity of about 50,000, though the contract recently let covers only about half the depth of the structure shown herewith or at the line indicated by the middle aisle running entirely around the stadium. This construction will be twenty-eight rows of bench seats with two rows of box chairs in front having a capacity of about 22,000. Considerable grading will be necessary in the construction inasmuch as there is no level piece of ground anywhere on the campus sufficiently large for an athletic field. The Osborn Engineering Co. who designed the structure was able to select a location in a hollow where advantage could be taken of the grading and the larger portion of seats constructed on ground either excavated or filled. A contract was awarded to the Bedford Steel Construction Co., Bedford, Ind., at a price slightly over \$4 per seat for the structure itself which does not include grading, plumbing, heating, lighting, drainage and incidentals. The price per seat excluding only grading will be about \$6.

Rapid Progress Made on the Oak Grove Power Project in Oregon

Rapid progress is being made on the Oak Grove project on the Clackamas River in Oregon where the Portland Railway, Light & Power Co. will develop 35,000 hp. in a single reaction turbine under a head of 850 ft. With a total of 1,700 men in the camps work has been carried on simultaneously on the several parts of the project.

The railroad has just been completed for its full length of 231 miles, using a maximum of 6 per cent grades and 40-deg. curves. Five geared locomotives are in service. The region is heavily timbered and it has been worth while to log off all areas that had to be cleared. On the transmission line particularly this has been an important item.

Work is under way on the 65-ft. diversion dam; grading has been completed for about 70 per cent of the 32,500-ft. pipe line that will consist, for the most part, of 9-ft. steel pipe, and about 4,400 ft. of this pipe has been placed. Work is well under way on the five short tunnels and loose material has been sluiced from the penstock and power house sites. The plant is to be finished and in service by the middle of next year.

H. A. Rands is in charge of design and construction for the power company; the Hurley-Mason Co. of Portland are the principal contractors.

Random Lines

"The Frogs"

By Our Federal Aristophanes

We reprint below, without comment, an authentic bit of inter-departmental correspondence:

TREASURY DEPARTMENT
INTERNAL REVENUE SERVICE
Louisville, Ky.

June 9, 1923.

To the gentleman to whom
this letter will be referred.

Dear Sir:

Can you inform me how to get rid of a frog chorus that performs every night, and all night long—most of the time, too, all day long, around a pond in a vacant lot next to my home?

They are first-class sleep destroyers and a great nuisance generally to everyone within two hundred yards of them.

The property has been taken over by the State for taxes, which makes any interference thereon red-tape, more or less annoying and more or less (principally more) a matter of time.

I have gone to quite some expense impregnating the pond to chase the frogs away, but they have absorbed everything so far and come up hollering for more.

Thanking you in advance, I am,

Yours sincerely,

R. O. DEPPEN.

June 14, 1923.

Mr. R. O. Deppen,
4700 S. 4th St.,
Louisville, Ky.

SUBJECT:

The bulldog on the bank and the
bulldog in the pool.

Dear Sir:

Your letter of June 9th, in which you ask how to get rid of a frog chorus, is one of the most pathetic that has ever come to this Bureau. Many persons enjoy toad choruses and would be glad to be in your shoes, or bed, just for the sake of hearing the nocturnal concerts about which you complain. It is a pity that Nature's music should not be appreciated.

Unfortunately, there are persons of an excitable and choleric temperament who instead of being lulled to sleep by the song of the innocent batrachians are greatly enraged by it. Apparently you are in this class, and we venture to make a few suggestions for your relief.

3. Try autosuggestion. Imagine that you are listening to the jazz band performing for your benefit, playing a lullaby or nocturne.

4. Incite a crowd of small boys to capture the larger frogs and turn loose in the pond a number of rattlesnakes to devour those that escape the boys. Perhaps a few lengths of garden hose, suitably painted and set around the banks at intervals, would serve as substitutes for real snakes. They might be called scare-frogs.

5. Your position in the Internal Revenue Service should make it easy for you to acquire plenty of the deadliest hooch. Have you tried impregnating the pond with that? If so, and the frogs came up for more, they are evidently steeped in the ancient traditions of the State and think that you are putting one of the essentials of life. The mint probably grows nearby.

6. There are various ways to deaden sounds. Most of them are probably not willing to sleep with closed windows in summer or to go to the expense of completely enclosing the pond in sound-proof walls. Besides, the State might shut the burden of paying the taxes to you, if you resorted to that extent. Maxim silencers might be effective, but they would be burdensome. Advice about these might come from the Public Health Service, Treasury Department, or from the Bureau of Chemistry, Department of Agriculture. We shall send your letter to the latter Department because it also includes the Biological Service.

7. These are but amateur suggestions for your relief. Frogs are not within the jurisdiction, but come under the Bureau of Biological Survey. Also, we do not work on drugs and poisons, and cannot recommend soporifics and sedatives for man or beast.

Respectfully,
GEORGE K. HESS, Director,
U. S. Bureau of Standards.

D-O Process for Trenton Again Disapproved

New Jersey Health Board Rejects Sewage Plans and Directs City to File New Ones Within a Year

Reiterating and expanding portions of its resolution of May 1, in which it refused to approve plans for treating the sewage of Trenton, N. J., by the direct-oxidation or lime-electrolysis process as drawn for the city by Col. George A. Johnson, consulting engineer, the State Board of Health of New Jersey again rejected the plans on July 31. The city was directed to file new plans within a year, these plans to comply with standard and accepted methods of sewage treatment and to contain only such elements as are necessary to comply reasonably with the policy stated in the Delaware River sewage zoning agreement between the New Jersey and Pennsylvania Departments of Health. (For the zoning agreement and for the Trenton sewage resolution of May 1, see *Engineering News-Record*, Aug. 10, 1922, p. 243, and May 31, 1922, p. 972.)

In its resolution of May 1, rejecting the plans then before it, the board advised Trenton that in its opinion sedimentation alone would be sufficient treatment for the sewage of that city for ten years and probably longer, or that in lieu thereof fine screening and lime treatment, with use of sludge thickeners, would do. The resolution also gave Trenton a month to reconsider the plans and afforded it a chance to re-submit the rejected plans for consideration by the board as for an experimental process. The Trenton City Commission accepted neither alternative. Instead, it again submitted the old plans for unconditional approval, accompanied by a resolution stating that it considered the direct-oxidation process the best and most satisfactory method of sewage treatment available.

The resolutions adopted by the New Jersey Board of Health on July 31 follow:

Whereas, The Board of Commissioners of the City of Trenton have, at their meeting held on June 8, 1923, adopted a resolution requesting the State Department of Health of New Jersey to approve plans for a sewage disposal works for the purpose of treating the sewage of Trenton and have expressed it as the opinion of said commissioners that the system of direct oxidation provided for in plans submitted to this Department for approval on Dec. 15, 1922, and referred back to the said commissioners by this department on May 1, 1923, for reconsideration, is the best and most practicable method for the City, and

Whereas, The proposed sewage disposal plant for the City of Trenton is to be constructed because of proceedings initiated by this department in the chancery court compelling action by the commissioners of the City of Trenton, and

Whereas, The Department of Health of the State of New Jersey in conjunction with the Department of Health of the State of Pennsylvania, on June 20, 1922, adopted a policy declaring, insofar as the policy affects the City of Trenton, that "Sewage discharged into the tidal portion of the Delaware River, from and including Morrisville and Trenton and to in-

To Build Vehicular Tunnels at New York City

Gov. Smith of New York has announced that he will recommend to the Port of New York Authority that it proceed at once to issue the necessary bonds to finance the construction of two vehicular tunnels under the Hudson River at New York City. Gov. Smith expects to confer with the Port Authority as to the location of these tunnels. They will be in addition to the one now under construction at Canal St. and will probably be located farther uptown; one will probably be in the neighborhood of 14th St.

To Use Old Canal Plane as Hydraulic Laboratory

The New Jersey Department of Conservation and Development is working upon a plan for the establishment of an hydraulic laboratory at the site of the old inclined plane of the Morris and Essex Canal near Boonton. The contemplated laboratory would be made part of the Rutgers College School of Engineering to be used in conducting tests on all kinds of hydraulic equipment. The site of the old canal plane is an ideal one, as such experiments can be carried out without interfering with the existing water power rights at that point. At the same time it will be possible to preserve the old plane.

cluding Philadelphia and Camden, shall be treated by means of sedimentation and the effluent discharged through submerged outlets into deep water in the Delaware River; . . . provided, that when plans for sewage treatment works are approved, where sedimentation of sewage is the only treatment required under this policy, the approval shall be subject to the condition that means for the further purification of the tank effluent shall be installed when deemed necessary by the State Department of Health.

Whereas, This Department is of the opinion, and so stated in a resolution passed on May 1, 1923, that the direct oxidation method of sewage treatment is still in an experimental stage and has not as yet been demonstrated as a practical and continuous method for the treatment of sewage, and is informed that the system has as yet not been endorsed or accepted by the engineering profession skilled in the treatment and disposal of sewage,

Therefore, Be It Resolved, That the Department of Health of the State of New Jersey does hereby reject the plans for the direct oxidation method as submitted by the City of Trenton and directs said city to file with this department, within one year, plans for a sewage disposal works in accordance with accepted and approved standards and methods for the treatment of sewage and containing only such elements as are necessary to comply reasonably with the terms of the policy adopted by the State Department of Health of Pennsylvania and the State Department of Health of New Jersey on June 30, 1922, above referred to, said new plans to be readily adaptable to providing additional means of purification later on if and when in the opinion of the Department that shall become necessary, provided, however, that the extension of time shall meet the approval of the chancellor.

Albany Appropriates \$600,000 for Filter Plant Improvements

An appropriation of \$600,000 has been made by the city authorities of Albany, N. Y., to overhaul the water purification plant and build a 10,000,000-gal. coagulating basin in accordance with recommendations of Allen Hazen, consulting engineer, New York City, in a report to F. A. Raven, commissioner of public works. The slow sand filters built over twenty years ago with Mr. Hazen as engineer are reported by Mr. Hazen as being still in good shape but new sand handling equipment and new orifices and gages are advised, the latter because of an increased rate of filtration. The scrubbers installed some years after the slow sand filters were built are to be repaired and improved; the old sedimentation baffled; some piping and Venturi meters added; the pumping plant changed; and dry-feed apparatus for alum provided at an estimated cost of \$29,000. There is an item of \$52,000 for wash-water pumps and tanks and \$40,000 for a new laboratory building and equipment. Extension of metering is advised as a readily possible means of still further reducing the per capita consumption so the original slow sand filters, operating at an increased rate due to the preliminary treatment—coagulation, sedimentation and rough filtration—may suffice for years to come. Possible new sources of supply, with particular references to gravity supplies, are reviewed but no specific action to this end is advised.

Civil Service Examinations

UNITED STATES

For the U. S. Civil Service examinations listed below, apply to the United States Civil Service Commission, Washington, D. C., or to any local office of the Civil Service Commission.

Hydrographic and topographic draftsman—Vacancies in the Coast and Geodetic Survey, at an entrance salary of \$1,400 a year plus the increase of \$20 a month allowed by Congress, and vacancies in positions requiring similar qualifications.

Hydrographer—Vacancy in the Reclamation Service at El Paso, Tex., and Powell, Wyo., at salaries ranging from \$1,680 to \$1,920 a year, plus the increase of \$20 a month allowed by Congress, and vacancies in positions requiring similar qualifications.

Applications for both must be filed with the Civil Service Commission, Washington, D. C., by or before Sept. 11, 1923.

Tunnel Contractor's Claim for Extras Denied by Higher Court

Reversing a decision rendered by the federal district court a year ago, the U. S. Circuit Court at Boston last week denied the claim of Patrick McGovern for extra compensation because of encountering a ledge of rock in digging the Dorchester tunnel. The case has been in the courts for five years. It was dismissed by the Massachusetts Supreme Court in 1918, and later was carried into the federal courts. A master appointed by the district court found in favor of McGovern, awarding him \$135,000 compensation, and this award was confirmed by the court. On the city's appeal to the circuit court this decision has now been reversed.

Engineering Societies

Calendar

Annual Meetings

NEW ENGLAND WATER WORKS ASSOCIATION, Boston, Mass.; Annual Convention, Burlington, Vt., Sept. 18-21, 1923.

INTERNATIONAL ASSOCIATION OF STREET SANITATION OFFICIALS, Chicago, Ill.; Annual Conference, Chicago, Sept. 27-28, 1923.

AMERICAN PUBLIC HEALTH ASSOCIATION, New York; Annual Meeting, Boston, Oct. 8-11.

AMERICAN SOCIETY OF CIVIL ENGINEERS, New York; Fall Meeting, Richmond, Va., Oct. 15-17.

AMERICAN SOCIETY FOR MUNICIPAL IMPROVEMENTS, St. Petersburg, Fla.; Annual Convention, Atlanta, Ga.; Nov. 12 to 16.

Personal Notes

F. H. COTHRAN, formerly resident manager of the Quebec Development Co. and the Alma & Jonquiere R.R., is now vice-president of these companies at St. Joseph d'Alma, Province of Quebec. The Quebec Development Co. is building a 480,000-hp. hydroelectric development on the Saguenay River.

V. A. KAUFMAN has been appointed assistant chief engineer on the Moffat Tunnel Work. He is the man who had charge of the original survey for the commissioners and supervised the drawing up of the plans and specifications. Mr. Kaufman is a civil engineer graduate of Ohio Normal University. He has had charge of various railway rock and tunnel projects in the West, and was for some time construction engineer for the Rio Grande, Sierra Madre & Pacific R.R. in Chihuahua, Mexico.

ROBERT HOFFMAN, city engineer of Cleveland, was tendered a banquet at Wade Park Manor recently by the members of his organization in honor of the completion of thirty years' service as the head of his department. The principal speaker of the evening was former Secretary of War Newton D. Baker.

A. W. ZESIGER, formerly bridge engineer for Cuyahoga County, has recently been appointed by State Highway Director L. A. Boulay as chief engineer of bridges. Mr. Zesiger assumed his new duties in Columbus Aug. 1.

CARL J. SITTINGER, for the past four years associated with John A. Stevens, consulting engineer, of Lowell, Mass., is now engineer in the Electrical Division of Stone & Webster, Inc., of Boston, Mass.

JOHN B. BRAY, commissioner of public works, Raleigh, N. C., has been appointed city manager of Elizabeth City, N. C. C. C. PAGE has been elected commissioner of public works succeeding Mr. Bray.

GROSVENOR W. STICKNEY has been appointed city engineer of Wheaton, Ill., to succeed L. W. Ruddock, resigned. Mr. Stickney has been for some time assistant engineer with A. L. Webster, municipal and drainage engineer, of Wheaton.

FRANK C. SQUIRE, Portland, Ore., has been appointed engineer of the Western Group, President's Conference Committee, Federal Valuation of the Railroads in the United States, effective Aug. 1. Mr. Squire is at present valuation engineer of the Oregon-Washington R.R. & Navigation Co. at Portland.

PROF. HAROLD A. THOMAS, for eight years associate professor of civil engineering and for the past five years professor of hydraulics at Rose Polytechnic Institute, Terre Haute, Ind., has been appointed professor of theoretical hydraulics and of hydraulic and sanitary engineering at Carnegie Institute of Technology, Pittsburgh, Pa. Prof. Thomas obtained his C. E. degree from Columbia University in 1908. In his professional work he has served as a member of the engineering corps of the New York State Water Supply Commission, member of the engineering corps of the Great Northern R.R., assistant engineer for the Miami Conservancy District on flood-control work, and as consulting and practicing civil and hydraulic engineer at Terre Haute, Ind. He is a pioneer in concrete research work.

J. H. GANDOLFO, who joined the engineering department of the Power Corp. of New York and the Northern New York Utilities, Inc., of Watertown, N. Y., in 1922 has been appointed chief designing engineer of these organizations. Mr. Gandolfo was formerly with the Hudson & Manhattan R.R. Co., J. G. White Engineering Corp., Westinghouse, Church, Kerr & Co. and the Division of Architecture and Construction, State of N. J., and has had charge of the design and construction of many important structures in the United States and its possessions.

FRED R. WHITE, state highway engineer of Iowa, is now actively engaged in directing the affairs of the American Association of State Highway Officials. With the resignation of Charles J. Bennett, the State Highway Commissioner of Connecticut, Mr. White automatically succeeded in the presidency of the organization.

Obituary

JOHN P. LEO, who was street cleaning commissioner of New York City from January to November, 1921, died July 23 of heart disease at Pawling, N. Y., where he was visiting. Previous to 1921 Mr. Leo had served on the New York snow removal committee which handled the exceptionally heavy snowfall of 1921, and as chairman of the Board of Standards and Appeal.

EDWIN E. BAKER, of Greeley, Colo., one of the state's oldest engineers, died recently at the age of 78 years. Mr. Baker built the Riverside reservoir near Sterling, Colo., the Tarry Lake reservoir near Fort Collins, the Fort Morgan canal, and the Platte and Beaver canals near Brush, Colo. He was a native of Fort Wayne, Ind., and a soldier in the Civil War.

From the Manufacturer's Point of View

A Point of Contact
Between Maker and User of
Construction Equipment and Materials

Manufacturers Adopt Standard Size for Common Brick

Through the co-operation of the Division of Simplified Practice of the Department of Commerce the common brick industry has discarded a great variety of odd sizes of brick and established one standard size for the seven billion building brick produced every year in the United States. This size is approximately $8 \times 3\frac{1}{2} \times 2\frac{1}{2}$ in. The only exception now to be allowed is in the case of smooth-faced brick for special exterior use, in which a slight variation in one dimension only is permissible.

The common brick industry established the standard size some years ago, but experienced trouble because its standard was not insisted upon for public work and by many architects. With the Government now definitely supporting the industry in its efforts to standardize its product it is expected that before long all specifications will call for standard sized brick, to the great benefit not only of the brick industry but to all users of its product.

New Plant for Meter Company in Five-Story Building

On a 2½-acre plot of ground in the Brushton district of Pittsburgh, a five-story building is nearing completion which will contain the new offices and works of the Pittsburgh Meter Co., manufacturer of water and gas meters. Founded in the '80's, the company was first known as the Safety Appliance Co., later as the Fuel Gas & Electric Co.; since 1895 it has operated under its present name. The early types of gas meter manufactured by the company were the invention of George Westinghouse. The building which will house the new plant is 80x300 ft. In plan, five stories high and will provide a floor space of approximately 150,000 sq. ft. The building is served by a private siding from the Pennsylvania R.R.

Heavy Duty Truck Sales Increase

All sales records for the first six months of any year in the history of the General Motors Truck Co., Pontiac, Mich., were broken during 1923, according to a tabulation just completed. During the first six months of the present year, this company sold 171 per cent more trucks than during the same period of 1922; the figures show that the so-called heavy-duty models have grown in popularity during the last year.

During the first half of this year the company sold 284 per cent more heavy-duty trucks than during the corresponding period of a year ago. While national figures show that the 1-ton truck is by far the most popular model made by truck manufacturers, this company asserts that the heavy duty units are fast overhauling the 1-ton models.

Tests of Interlocks Point Way to Safer Elevators

About three-fourths of all fatal elevator accidents are found to occur at the hoistway door, either because of the door being opened when the elevator is not there or because of the elevator starting when the door is open. These accidents, according to the U. S. Bureau of Standards, can be prevented by a reliable interlock, as when such a device is used the elevator must be stopped at the floor before the door can be opened, and the door must be closed before the car can be started again.

During the past year the Bureau has been conducting tests to determine the

Chart Shows Trucks Needed With Mechanical and Hand Loading

By W. H. BOSWORTH
Field Sales Engineer, The Geo. Halsey
Manufacturing Co., Inc., New York

THE accompanying diagram shows the number of trucks required to haul a given daily yardage of material—sand, gravel, crushed stone, cinders or earth—for distances of $\frac{1}{2}$ to 10 miles, with hand loading and mechanical loading of trucks. Approximate average conditions are assumed: 9-hour day; 5-yd. trucks; loaded speed, 8 miles an hour; empty speed, 12 miles an hour; allowance for dumping, 1 min.; time of hand loading for sand, 17 min.; time of hand loading for stone, 25 min.; time of loading with truck loader, 4 min.

To illustrate the use of the diagram assume the case of a contractor who must deliver 300 cu.yd. of crushed stone daily with a haul (one-way) of 3 miles. How many 5-yd. motor trucks will he need if the loading is (1) by hand: (2) by mechanical loader?

DIAGRAM FOR DETERMINING NUMBER OF TRUCKS NEEDED WITH MECHANICAL AND HAND LOADING

A line drawn between the yardage to be moved per day on "Z", and the length of haul on "X", to the proper scale, A, B, or C cuts "Y" at the number of 5-yd. trucks required. Sim-

ilarly, a line from the haul on "X" through the trucks available on "Y" will meet "Z" at the yardage which can be moved with that combination of equipment.

reliability of the various types now on the market. The devices have been given endurance tests under normal conditions, they have been tested in a corrosive atmosphere, in a dust-laden atmosphere, without lubrication, and under conditions of misalignment likely to occur in practice. The tests were conducted at the request of the City of Baltimore, and will permit city governments to base their approval of such devices on actual performance tests instead of on visual inspection alone. The results have also been made available to the manufacturers of the devices tested, and in most cases they have improved their designs in accordance with the suggestions offered.

For hand loading: On left-hand scale, (Z) select point at 300 (yd. of material to be handled daily) and on right-hand scale (X-C, for broken stone) select point at 3 (miles of haul, one-way). Join the two points with straight line and at intersection of this line with middle scale (Y) read "8" trucks.

For mechanical loading: Repeat process, except use right-hand scale (X-A) instead of scale (X-C). The trucks needed in this case are shown to be "5", or a saving of 3 trucks with mechanical loading.

The rates of hand loading are for 6 men per truck and are about twice the daily average. The men will load

half the time and rest the other half. The rate of mechanical loading assumed will be equalled or excelled by any high-powered truck loader, mounted on caterpillars and with self-feeding device and crowding speed, in any loose material. Scale A, for the truck loaders, is also applicable to any other mechanical means of loading of the same approximate capacity, such as power-shovels, crane and clamshell bucket, etc.

The diagram is only true for the conditions assumed, but they are reasonable. It shows forcibly one reason why machinery is used so largely for loading which has not been stressed so much as the obvious one of saving in cost of actual loading, and that is the greater efficiency of the trucks. When 500 yd. of stone are to be moved each day, mechanical loading saves 5 trucks, each of which costs more to operate than the loading machine. As a matter of fact the money saved in this way is usually greater than the saving in cost of actual loading.

The answer for other conditions than those assumed can of course be approximated from the diagram. The number of trucks required will vary approximately inversely as their capacity. If the speed at which the trucks travel is not as assumed, the number required will vary approximately directly as the total round-trip time, including loading. Different loading rates can be interpolated approximately on the line X.

Report on Bethlehem Plan of Employee Representation

President Eugene G. Grace, of the Bethlehem Steel Co., made public July 27 the first report on the results of the plan of employee representation which has been in effect at the plants of the company since 1917. Of the 2,365 cases which actually reached the employees' representatives in committee and in some instances reached joint committees as well, 1,682, or 71 per cent, were settled in favor of the employees. In the Bethlehem plan elected employee representatives operating by themselves, with negotiating powers through committees of their own choosing, and also in appeals through joint committees with appointed management representatives, pass upon every matter arising out of the employment relationship which has not been satisfactorily settled in the first instance with the ordinary plant authorities for individuals or for groups.

Three hundred and thirty cases raised by employees, or 14 per cent of the total, were settled in the negative, most of them in the first stage by the employee representatives' own committee, without the complainant availing himself of the appeal provisions of the plan. Over 201 cases, or 8.5 per cent, were withdrawn by the employees concerned after the facts were brought out. Over 103, or 4 per cent, were compromised, and only 49 were pending settlement in four large plants using the plan.

Since the inauguration of the plan in 1917, 2,365 cases have been adjusted; 612 of these cases, or more than one-fourth were directly concerned with employment and working conditions; 570 other cases which came up for adjudication dealt with wages, piecework, bonus and tonnage scheduled,

Simplified Asphalt Grades Win Endorsement

Substantial progress has been made in securing endorsement by both asphalt producers and consumers of the simplified scale of 10 grades (as determined by penetration limits) adopted at the joint conference with the Division of Simplified Practice of the Department of Commerce held in Washington, D. C., May 28.

"Engineering News-Record" has received from the Department of Commerce the following report on the status of the movement for fewer grades:

"To date (July 30, 1923), we have received acceptances to the asphalt simplification from the Asphalt Association, which speaks for its entire membership, the American Society for Testing Materials, and 15 out of 48 state highway engineers. This indicates that the project is going smoothly and we are in hopes of getting the remainder of acceptances from the engineers within the next two weeks."

Committee Names Three Sizes for Tilting Mixers

The Joint Committee on Construction Equipment, at a meeting held in Chicago this week, recommended for adoption as standards three sizes—31, 5 and 7 cu.ft.—of concrete mixers of the tilting type.

The committee, at its previous meeting, June 27-29, considered only the non-tilting type of mixer, recommending four sizes of building mixer—7, 14, 21 and 28 cu.ft.—and three sizes of paving mixer—7, 12 and 21 cu.ft., as reported in *Engineering News-Record* of July 5, p. 36 and July 19, p. 120.

Business Notes

WESTERN WHEELED SCRAPER Co., Aurora, Ill., announces that W. G. Sharretts has been transferred from the Atlanta territory to take charge of the New York Office. He will have charge of the company's domestic sales in the Eastern territory with contractors as well as industrial and railroad companies, selling arrangements heretofore existing in New York having been cancelled.

GINSBERG-PENN Co., Inc., New York, sales representatives for construction machinery, has been appointed, effective Aug. 1, to take on exclusive distribution of the line of locomotive auto and Truckranes manufactured by the Byers Machine Co., Ravenna, Ohio. Frank I. Ginsberg, president of the distributing company, was

formerly with the R. E. Brooks Co. and the Insley Manufacturing Co., Hamilton, O. Penn served with the T. L. Smith Co.

VULCAN IRON WORKS, Wilkes-Barre, Pa., announces the appointment of Thomas MacLachlan as manager of its New York office, succeeding M. E. Davis. The company manufactures locomotives, electric hoists, steel castings, cement mills, coolers and dryers.

CLERMONT CLAY PRODUCTS Co., Philadelphia, has been organized to take over the plant and property of the International Clay Products Co., manufacturing underground conduits at Clermont, Pa.

A. S. MOODY, assistant Northwest manager of the General Electric Co., Schenectady, N. Y., has been appointed local manager of the Los Angeles office of the same company, to succeed R. L. Cash, who has been transferred to Schenectady. Mr. Moody has been identified with the General Electric Company on the Pacific Coast section for the past 16 years.

Equipment and Materials

Safety Clamp for Wire Rope

For fastening wire rope a clamp with a U-bolt and self-tightening cam which it is claimed cannot slip or crush the cable, is being manufactured by the Mal-Gra Casting Co., Cambridge City, Ind., under the trade name of the Keator safety clamp. The clamp, as shown in the accompanying illustration, is applied square with the cable and tightened with a wrench. A feature of the device is the use of a grooved cam which serves the double purpose

of protecting the cable from the concentrated pressure of the U-bolt and of providing an eccentric movement which causes it to increase its grip as the cable turns it under pressure. Only one clamp of the Keator type is said to be required for each cable. The self-tightening feature it is pointed out automatically compensates for the shrinkage of the cable under load, and merely grips the tighter as the load increases.

New 14-Yd. Heavy-Duty Shovel

To its line of revolving steam shovels, the Osgood Co., Marion, O., has added a new 14 yd. heavy-duty model of the full revolving type, mounted on crawler treads. The shovel, designed for heavy work, has over-sized castings and large bearing surfaces at points of great stress. The boom and dipper handles are built up of white oak timber shrouded with plate steel and the whole securely bolted to form solid units. Double gearing on the dipper shaft insures equal application of power to the dipper handle racks, eliminating side strain and twisting. The continuous tread mounting has an all-gear drive. In general design, the machine is patterned after the Osgood 3-yd. shovel.

Quick-Acting Solenoid Brake for Crane Service

A quick-acting, powerful solenoid brake has been designed especially for crane service by the Whiting Corp., Harvey, Ill. The brake arms are so pivoted that the shoes release equally at all points, preventing dragging. The shoes are cast iron filled with a shocble and heat-resisting asbestos composition. To take out the shoes it is only necessary to remove four cap screws and pry the shoe out. Under ordinary conditions, the manufacturer states, adjustment is required only once a month.

The brake is made in both direct-current and alternating-current models. On

the former, the plunger is of soft iron of large diameter, giving a fast operating solenoid even at light loads. The d.c. coils are designed to operate the brake at about 40 per cent full load current and remain open at 10 per cent or less full load current. The voltage lost in the coil in most averages less than 4 per cent, and in no case more than 7 per cent. On the alternating-current type, the plunger is of laminated iron of proper thickness for the service intended.

For test purposes a 12-in. brake was mounted on a 25-hp., 550-r.p.m., direct-current motor. The motor was stopped 50,000 times at a rate of 325 stops per hour without resulting in excessive wear of the brake shoes.

Publications from the Construction Industry

Rolling Steel Doors—J. G. WILSON CORP., New York, in a 72-p. illustrated catalog explains the design and operation of its rolling steel doors and illustrates the variety of their use in industrial and commercial buildings. The standard doors are made of slats of open-hearth or copper-bearing steel which are raised or lowered by winding on a shaft operated either by hand or electric motor. Among typical installations shown in about 30 pp. of photo graphs are warehouses, car barns, railway shops, power stations, freight stations, docks factories and airplane hangars.

Waterproofing—GARDINER & LEWIS, INC., New York, has published a 32-p. pamphlet, illustrated, dealing with the principles underlying the manufacture, use and specifications for bituminous materials employed for waterproofing. A number of specific waterproofing problems are presented, with drawings, in which the use of the company's Kar-nak membrane waterproofing is employed in buildings, swimming pools, reservoirs and dams, and steel and concrete bridges.

Business Side of Construction

FACTS AND EVENTS THAT AFFECT COST AND VOLUME

N. Y. Builders Increase Support for Apprenticeship Work

An appropriation of \$25,000 has been made by the New York Building Trades Employers' Association to the New York Building Congress for the work of the Apprenticeship Commission during the ensuing year. This represents a material increase over last year's appropriation of \$8,000 by the same body for this purpose.

It is anticipated that the local labor organizations also will again contribute to the work of the commission as they did last year.

This enterprise is a joint undertaking of the building trades employers, building trades labor and the city educational authorities to provide a systematic training for apprentices in the several building trades. Its work was described and discussed at greater length in *Engineering News-Record* of Jan. 11, 1923, p. 62 and April 19, 1923, p. 695.

Lumber Movement Gains

The nation's lumber business for the week ending July 21 showed an appreciable gain over the preceding week, according to the weekly review of the National Lumber Manufacturers Association. With only 408 of the larger commercial mills of the country represented, as compared with a revised total for 423 for the preceding week, new business, shipments and production showed gains. As compared with last year the week also showed advances in all three factors. The 137 Southern pine mills gave their unfilled orders as 250,985,085 ft. as compared with 252,785,610 ft. the preceding week and 128 West Coast fir mills gave their unfilled orders as 306,985,928 ft., as against 349,761,933 ft. the week before, the net decline in unfilled orders for both groups taken together being 44,576,530 ft.

For all the reporting mills shipments were 87 per cent and orders 78 per cent of actual production. For the Southern pine mills these percentages are respectively 90 and 87 and for the West Coast mills 100 and 90. Most of the mills have an established normal production figure for the week, in relation to which actual production was 107, shipments 95 and orders 86 per cent.

The following table gives the lumber movement for the week ending July 21, the corresponding week of 1922 and the preceding week of 1923 for purposes of comparison:

Mills	Week Ending July 21	Corresponding Week 1922	Preceding Week 1923 (Revised)
Production, ft.	273,971,556	224,334,859	263,369,278
Shipments, ft.	238,532,807	214,745,867	231,913,698
Orders, ft.	214,822,645	206,982,446	208,265,237

The following table compares the reported lumber movement for the first 29 weeks of 1923 and for the same period in 1922:

	Production, Ft.	Shipments, Ft.	Orders, Ft.
1922....	7,102,633,635	7,331,430,859	7,220,550,231
1923....	5,901,915,595	5,997,527,955	6,357,825,589
1923			
Increase	1,200,718,040	1,333,902,904	862,724,642

Million Mark Again Passed in Freight Car Loadings

Loading of revenue freight for the week which ended on July 14, according to the Car Service Division of the American Railway Association, totaled 1,019,667 cars. This total fell short 2,103 cars of equalling that for the week of June 30 this year, when 1,021,770 cars were loaded, the greatest number for any one week in the history of the railroads, but this was the second time within three weeks that the previous record, which was made during the week of Oct. 14, 1920 at which time 1,018,539 cars were loaded, has been eclipsed.

Including the week of July 14, the million-car loading mark has been exceeded in six out of eight consecutive weeks so far this year, the average loading for the six weeks being 1,013,118 cars. In 1920, the million-mark was reached only on five occasions and then only in the fall of the year. The average for those five weeks was 1,009,688 cars. The million mark was reached in only two weeks in 1922, but never attained in 1921 or in any week prior to 1920.

From Jan. 1 this year to July 14, inclusive, 25,887,240 cars were loaded with revenue freight. This was an increase of 4,309,272 cars or 20 per cent over the corresponding period last year, and an increase of 5,785,900 cars or 28.8 per cent over the corresponding period in 1921. It also was an increase of 2,676,475 cars or 11.5 per cent over the corresponding period in 1920. In making comparisons with last year, however, consideration must be given to the fact that coal shipments were curtailed by the miners' strike which began on April 1, while on July 1 a strike of railway shopmen also went into effect, both continuing until early fall.

Malleable Castings

The Department of Commerce announces statistics on the production of malleable castings manufactured for sale during June, 1923, as shown by reports received by the Bureau of the Census. The figures for May are revised to include reports received since the preliminary bulletin for that month was issued. The returns include only those castings manufactured for sale as such and do not include those used in the plant or finished and sold as other products.

The returns for June include 96 establishments and show that during the month these plants were operated 67.3 per cent of their total capacity. The revised figures for May include the production of 90 establishments which were operated 71 per cent of their total capacity during the month.

Month	Plants Reporting (Number)	Total Production (Tons)	Total Shipments (Tons)	Orders Booked (Tons)	Monthly Capacity of Plants (Tons)
June.....	96	61,949	61,441	38,536	92,004
May.....	90	64,726	62,806	52,898	91,174

July Contracts Over Thirty-Six Per Cent Heavier Than for Corresponding Period in 1922

Falling Off of Thirteen Per Cent Compared With June Awards—Gains in Bridges, Excavations, Streets and Roads

The total value of contracts awarded on large engineering construction projects during July, totaled \$163,459,000 as against \$188,786,000 for the preceding month. This represents a drop in actual money value of over 13 per cent in one month. Compared with July of last year, however, a gain is noted of somewhat over 36 per cent.

The number of awards totaled 755 during July, with an average value of \$216,502 as compared with 816 in June, averaging \$231,355.

Minimum costs observed in Construction News on each class of construction are as follows: Water-works, \$15,000; other public works, \$25,000; industrial construction, \$40,000; and commercial buildings, \$150,000.

Of the \$163,459,000, a total of \$8,436,000 represented Canadian awards, which fell off 20 per cent during July.

All classes of construction fell off during July except bridges, excavations and streets and roads. July bridge contracts nearly doubled those of June in total money value, although no single project reached above \$780,000. Excavation, drainage and irrigation lettings gained heavily. Increases in these classifications were induced by several large jobs such as the four track subway at Rochester, N. Y., valued at \$1,654,765 and a portion of two tunnels, approaches to river section of Hudson River Tunnel, \$3,467,414. Streets and roads awards gained over 10 per cent during the month.

Bids Wanted on Big Jobs

Among the projects on which bids are either asked or will soon be called for, in Construction News, pp. 61 to 73, are the following:

Temple, Louisville, Ky., for Kosairs Association, \$1,000,000.

Foundation, Minneapolis, Minn., for H. S. Gollie, agent, bids on superstructure at later date, total cost \$1,300,000.

Railway, Manitoba, Canada, from Beaconia to Ft. Alexander, for Manitoba Pulp and Paper Co., Ltd., \$3,000,000.

Large Contracts Let During Week

Among the week's announcements of contracts awarded in Construction News, pp. 61 to 73, are the following:

Medical Association building, Seattle, Wash., to Great Northern Construction Co., \$1,800,000.

Subway, Philadelphia, Pa., to Keystone Construction Co., \$1,198,555.

Engineering News-Record Construction Cost Index Number

August, 1923	221.50
July, 1923	222.10
August, 1922	173.40
Peak, June, 1920	273.80
1913	100.00

Engineering News-Record's Construction Cost Index Number declined 0.6 points since last month due to drop in lumber. Prices of other basic materials remained unchanged during month. The average rate for common labor is still 54c. Thus, general construction cost is 28 per cent higher than one year ago and 19 per cent under the peak; it is 121 per cent above the 1913 level.

Engineering News-Record Construction Volume Index Number

Monthly	
July, 1923 (4 issues of E. N.-R.)	128
June, 1923 (4 issues of E. N.-R.)	148
July, 1922 (4 issues of E. N.-R.)	118
1913	100
Yearly	
1922 (entire year)	130
1921 (entire year)	88
1920 (entire year)	91
1913	100

Engineering News-Record's Construction Volume Index Number is 128 for the month of July, and 130 for the whole of 1922, as against 100 for 1913. This means that the actual volume of construction in 1922 (not the mere money-value of the contracts let that year) is 30 per cent above the volume of construction for 1913. Our monthly volume number, 128 for July, 1923, is really the increment of construction, and indicates the rate at which contracts are being let as compared with 1913 awards.

VALUE OF CONTRACTS LET IN THE UNITED STATES AND CANADA DURING JULY, 1923

	New England	Middle Atlantic	Southern	Middle West	West of Mississippi	Western	Total United States	Canada	Total
Waterworks		\$612,000	\$195,000	\$1,925,000	\$867,000	\$59,000	\$3,658,000	\$145,000	\$3,803,000

Labor Rates and Conditions Throughout the Country

Industrial operations, generally are proceeding at a rate somewhat over 80 per cent of capacity. The slowing down process now in effect in certain industries is purely seasonal, while in others the reserve materials stocks have apparently reached a point adequate to current trade requirements.

According to latest reports of the United States Department of Labor, employment shows decreases in the following basic industries: paper and

printing; vehicles for land transportation; stone, clay and glass products; textiles; iron, steel and other metals.

Increases, however, were noted in the following: leather; lumber; beverages; food; railroad repair shops; tobacco and chemicals.

Wages paid common laborers, pick and shovel men in construction operations, remain at the July rate of 54c. as against 53c. per hr. during June, according to *Engineering News-Record*

figures. Local building conditions are as follows:

Atlanta—Building permits indicate that peak has been reached; slowing down expected.

Baltimore—Scarcity of bricklayers, carpenters, hod carriers and common laborers. Conditions otherwise normal.

Boston—Scarcity of bricklayers, carpenters, and pile drivers; plenty of other crafts. Bricklayers attracted to New York by higher wages. Minimum

CURRENT BUILDING TRADES WAGE RATES PER HOUR

(Higher rates indicated by +, decreases by —)

Cities	Brick-layers	Carpenters	Hoisting Engineers	Hod Carriers	Pile Drivers	Structural Iron Workers	Common Labor
Atlanta	\$1.12½	\$0.90	\$0.70	\$0.50	\$0.75	\$0.30@.35

rate to hoisting engineers advanced 25c.

Dallas—Excessive demand for bricklayers. Slight unemployment in common labor.

Detroit—Conditions normal in all trades.

Kansas City—Scarcity of bricklayers and carpenters; plenty of other crafts.

Montreal—Scarcity of bricklayers; carpenters not plentiful. Ample supply of other trades. Common labor wage rate at maximum of 30c., against 35c. per hr., last month.

New Orleans—Carpenters on strike since July 17, demanding "closed shop"

at present rate or \$1 per hr. with "open shop" conditions. No other crafts have struck in sympathy, as anticipated. Exodus of negro labor to North seriously affecting agricultural interests.

New York—All trades working. Construction has fallen off to a degree consistent with the supply of labor. Cement workers called off strike, accepting 93c. as against 81c. per hr. Difficulty experienced in obtaining bricklayers to work on school construction at established rate of \$12 per day, when other building operations offer as high as \$16. Tendency toward cost

stabilization has prompted builders to lift ban on new construction projects.

St. Louis—Shortage of bricklayers and hod carriers. Carpenters union has voted to demand \$1.50 per hr., an advance of 25c. The union has no contract with the builders. Jurisdictional dispute exists between carpenters and metal workers as to installation of metal trim. Bricklayers, structural iron workers and common laborers receiving higher wages than month ago.

San Francisco—All building crafts busy. Active construction program in sight.

Monthly Prices of Construction Materials

Ups and Downs of the Market

Pig Iron—Birmingham base on No. 2 foundry, \$25 as against \$27 per gross ton, one month ago. Lower prices tempting heavier volume of inquiries. New buying continuing on better scale but in small tonnages. Foundry and bessemer expected to develop firmer tendencies.

Railway Supplies—Track accessories in good demand; prices firm at July levels. Slight downward tendency in rerolled rails at Pittsburgh.

Pipe—No changes in prices of wrought steel and iron pipe, cast-iron pipe and clay drain tile. Buying of merchant steel pipe improved. Sewer pipe advanced slightly in Dallas and declined in Atlanta, during month.

Road and Paving Materials—Crude oil output at new high mark. Road-oils' prices unchanged. Bulk asphalt declined slightly in Boston and Cincinnati. Granite paving blocks, 5-in., dropped \$5 per M. in Boston. Wood-block paving declined slightly in Boston and New York.

Sand, Gravel and Crushed Stone—Gravel, 3-in., dropped 50c. in New York, 10c. in St. Louis and advanced 13c. per cu.yd. in Dallas, during month. Sand

declined 6c. in Dallas and 10c. per ton in Cincinnati. Crushed stone remained firm in nineteen cities reporting to *E. N. R.*, with the exception of a slight advance in St. Louis.

Lime—Boston and Atlanta report declines both in hydrated and lump. Common lump, however, advanced sharply in San Francisco. New York prices remain unchanged despite shortage of finishing lime.

Cement—Mill prices firm. Price advanced 10c., f.o.b. Boston and Kansas City and 11c. per bbl. in Duluth, Minneapolis and St. Paul. San Francisco, however, reports drop of 8c. per bbl. in month.

Structural Steel—Buying on the increase, particularly in plates. Oil-storage tank, car materials and track accessories requirements taking bulk of business. Price of plates and shapes firm at \$2.50 per 100 lb., Pittsburgh, for shipments at convenience of mill; as high as \$2.60, however, obtained for small lots, or where immediate deliveries are required. Structural inquiries better; confined to small tonnages.

Brick and Hollow Tile—Common

brick advanced from \$20 to \$21@ \$22 per M., wholesale, alongside dock, New York, since July 5. Slight rise also reported in Birmingham. Brick dropped 50c. in Boston; \$1 in Detroit and \$2 per M. in Atlanta. Hollow tile declined in St. Louis and Atlanta, and advanced slightly in Boston, during month.

Lumber—Price tendency continues downward throughout the country owing to decrease in demand. New York reports drop of \$1 and Chicago, \$2 per M. ft. in yellow pine timbers, during month. Declines also reported in New Orleans, Atlanta, Dallas and Birmingham. Slight advances, however, developed in Boston, Baltimore, Denver, Minneapolis, Kansas City and Detroit.

Explosives—Dynamite, 40 and 60 per cent gelatin, declined in Dallas and Minneapolis, and advanced in St. Louis, during month.

Scrap—Iron and steel scrap lower than month ago in New York and St. Louis. Firm at present levels.

Linseed Oil—Raw oil dropped 8c. per gal. in New York since July 5. Chicago prices unchanged in month. Tendency downward in Atlanta, Dallas, Minneapolis and Denver.

Price advances since last month are indicated by heavy type; declines by italics.

A Man Departs

HE CAME to power when the world was out of joint; his was the heavy task of setting it right. Small wonder that he was not able in the brief two years allotted him to build up the broken body. The healing of the economic and political wounds made by a great war is a long process and doctors and specifics can do little to hasten it. His was the temperament which put its trust in calm and order, which distrusts the unusual and loves accord. There are those who would have had more of the iron hand in his velvet glove, a more spectacular and emphatic program for relief, but who can say which of the two courses will lead to the most speedy cure? One thing remains; a man has gone, a lovable personality, a personification of the American ideal of rise from obscurity to the great place of the nation. To all of us, from those scattered settlers in our far northern outposts who last saw him in his prime, to the busy workers in our crowded cities who were shocked by the headlines last Friday morning, there will remain the inspiration of his kindly spirit. And this is Warren Harding's greatest legacy to the people he was chosen to lead.

A Prophecy?

IT WAS at the reconstruction congress of governors and mayors called by President Wilson in March of 1919. There was a rather crowded buffet luncheon served that day in the large state dining room of the White House, where only standing room was available except for a few chairs ranged against the walls. In one of these, the great, high-backed, eagle mounted mahogany quite evidently reserved for the President's use at the head of his own table, sat a man clad in the severest of black relieved only by the white of linen—a curiously pallid face intensified by his smooth, plastered taffy colored hair. An unnatural seriousness seemed to overburden him. So strange he looked that one of the editors of this journal who was there was moved to ask who he was. "Why," was the answer, "that's Coolidge of Massachusetts."

New Structural Possibilities

TO THE ENGINEER familiar with steel construction the use of material of sheet-metal thickness in large engineering structures necessarily appears so far outside the range of practical possibility as to be wholly out of relation to his engineering thinking. The rust danger makes it imperative to use thick sections, and in consequence the entire habit of structural practice and structural thinking is predicated on thick material. The engineer is likely to carry his conclusions farther, however, to the extent of believing structural framing of thin material to be impracticable from the standpoint of strength and all but impossible from the fabricating

standpoint. In the airship just completed at Lakehurst we have convincing proof that such conclusions are wrong, and correspondingly the work is of remarkable instructional and stimulative value. The successful solution of all fabricating difficulties shows clearly that shop requirements do not fix a lower limit of thickness. And on the question of strength, several hundred tests of members of the airship, showing very high strengths in column, beam, and combined service, have established the fact that this sheet-metal structural work can be developed to substantially as high a strength efficiency as we expect in ordinary structural steel members. The Navy Department is entitled to the thanks of the structural engineering profession for making available an account of its construction experiences, and it is to be hoped that the test results also will be placed before the profession soon. The building of the ZR1, as described in some of its technical aspects in this issue, is certain to exert a strong, progressive influence on the development of thought in the structural field.

The Port of San Francisco

WITH the recent adjournment of the California legislature, the fight to prevent taking control of the San Francisco waterfront away from the state and giving it to the city has again been won. The case for the state is so clear that it will bear study. Two navigable streams empty into San Francisco Bay, and together drain a valley 500 miles long with 10,000,000 acres of fertile land of which about 5,000,000 is now under irrigation. These rivers, therefore, serve a useful transportation purpose in delivering produce to a central market or shipping point. Under these conditions a port becomes something in which many shippers have a vital interest and in whose management and control they are entitled to have some influence. Under state management the facilities provided on San Francisco's waterfront for the distribution and export of produce have encouraged the development of farms and factories in the great central valley. Without such facilities the products of those farms and factories could not be profitably marketed. Should control of the port be transferred from the state to a small part of the area from which the traffic of the port is drawn, the remainder of the area would have to take chances on getting necessary concessions.

State Harbor Control

ON ONE point San Francisco has ground for dissatisfaction with the present arrangement. The east bay cities are not under the jurisdiction of the State Board of Harbor Commissioners, and they are therefore in a position to compete as they please for the business of the port. San Francisco, being unable to dictate waterfront policies, rates, etc., as do the cities across the bay, feels itself to be the victim of discrimination. Although a large percentage of the

business of the port as a whole is still handled on the San Francisco side of the bay, east bay cities have grown rapidly and it is highly important that some way be found to prevent rivalry between bay cities that is not in the best interests of the port as a whole. Rather than to vest full port control in the city of San Francisco the state jurisdiction should be extended to all the bay cities with some proportional representation and some measure of local veto which would prevent unfair domination by state interests not connected at all with the port. This has been done by interstate control at New York, though as yet the results have been disappointingly small, it has existed for years at Boston, it doubtless will eventually be brought about at Philadelphia. There is no similarity between the usual demand for home rule of cities and the demand which San Francisco and New York make for release from state authority in their ports. Property interests, through their sinister representatives, the real estate men, seem to assume that possession of some waterfront land gives autocratic rights to a harbor. That is wrong in principle; the port is merely a gateway for the state and the country and its administration can not be hampered by the selfish claims of those who happen to live at the gate.

Promotion and Ethics

NOW that the Trenton plans for sewage treatment by the direct-oxidation process have again and finally been rejected by the New Jersey State Board of Health, attention may be turned from the process itself to some ethical aspects of the promotion methods employed in an attempt to hasten action by the board. These are of direct concern not merely to other state health departments but also and more deeply to engineers, since the promoters, besides charging the entire New Jersey board with holding up the plans, laid the onus on one of the two engineer-members of the board and were backed in this by Col. George A. Johnson, consulting sewage-works engineer for Trenton.

The charges submitted to Governor Silzer by Mr. Hirst last February, Mr. Potts' denial, and a summary of what was brought out at the hearing have been detailed in previous issues of this journal. As modified and explained at the hearing, the charges come down to this: Because the Trenton plans had been before the New Jersey Board of Health for two months without final action, and because Mr. Hirst had heard indirectly that Mr. Potts had expressed himself as against approving the plans, and since Mr. Hirst could explain all this to his own satisfaction in no other way than that Mr. Potts was out for "revenge" because he had been denied an interest in the direct-oxidation process, Mr. Hirst decided "to throw the full light of publicity" on Mr. Potts and so brought the charges in question. Colonel Johnson initialed each paragraph of the charges except those alleging motive, but he did not appear at the hearing to substantiate his joining in the charges. Nor did Mr. Hirst offer any testimony whatever to establish his allegation that the other ten members of the board had been induced to join Mr. Potts in holding up the plans, nor that it is at all unusual for a state health department to defer action on sewage-works plans for two months.

This is promotion run mad. It is all the worse because it was seconded by a consulting engineer in a

way that seems to have been shrewdly designed more to evade possible punishment under the law of libel, than with that high regard for professional ethics that should accompany technical ability. Trying to discredit engineers and to bully and defy state health departments who are skeptical or seem unduly slow in approving plans is hardly the way to establish the direct-oxidation method of sewage treatment, which, like hundreds of others that have been promoted in the last half century, will have to take its place on merit or fall by the wayside.

Traffic on Bridge Approaches

MOTOR traffic has set up entirely new capacity standards for streets and bridges. It is obvious that the greater loads from the heavy motor trucks entail new considerations of load bearing capacity from those held in the days of horse-drawn vehicles, but it is not always remembered that the much greater number of vehicles and their higher speed, both due to the introduction of the motor, have brought with them new problems of space and volume capacity. There is much yet to be done in traffic analysis with relation to roadway width, particularly in the spacing and speed of vehicles for the maximum capacity of a given thoroughfare.

Bridge approaches offer an excellent illustration of this new development. In planning the new vehicular bridges for Portland, Ore., for instance, special attention is being given approaches in the belief that by providing a traffic capacity on approaches greater than that heretofore considered necessary, the result will be a considerable increase in the rate at which the structure as a whole can handle traffic. This point of view is summarized in a comment on Portland's existing bridges (built before motor traffic had become heavy) by the engineers in charge of the new structures that "There is not a single bridge in Portland today that is being used to as much as one-half of its capacity on account of the fact that the approaches in all cases are inadequate to get the traffic on or off the structures."

In planning the new structures effort is being directed toward developing the full capacity of the bridge by approaches of suitable design. The theory on which this is being done is that at the last cross-street the bridge traffic is slowed up, and in fact during the rush hours is frequently brought to a full stop, by the cross-traffic. The bridge traffic therefore is assumed to be entering the bridge approach from a standing start or at a relatively low speed and, according to the ability of the cars to accelerate, will require some considerable distance to attain the speed that gives the maximum capacity on the bridge. If several hundred feet is required to attain that speed, then the approach must be wider than the bridge for that distance in order that the capacity of the approach, on which the average speed of the cars is less, may equal the capacity of the bridge itself, over which the maximum capacity speed is maintained. On the new Burnside bridge five lanes of traffic each way on the approaches are to be converged to three lines on the bridge proper by marking the converging limits of the traffic lanes on the roadway.

In making their bridge capacity studies the Portland engineers disagree with the conclusions reached by Herbert S. Swan and published in *Engineering News-Record*, Feb. 22, 1923, to the effect that a speed of 10 miles per hour, because of the greater spacing required

at higher speeds, gives the maximum capacity, i.e., the maximum number of cars past a given point in a given time. The Portland engineers believe that a higher speed (something like 20 miles per hour) and a closer spacing are safe. The theory in support of this is that it is impossible for any car to come to a full stop instantly and that assuming the greater rate of deceleration in the car ahead (which is the more dangerous situation) the safe spacing would be determined by the relative rate of deceleration of the two cars plus a distance to allow time for the driver of the car behind to get warning that the car ahead is slowing down.

The whole problem is so involved with the human equation and with such widely varying conditions that no mathematical formula can give an exact solution. Moreover, any theoretical solution must be checked with actual conditions in traffic because it is not so much what spacing and speed is best as it is what spacing and speed can be secured, all things considered. Even when theory and practice are co-ordinated it may be that more efficient brakes—such as the four-wheel brakes that are rapidly coming into vogue—or some other factor may require complete revision of the conclusions. It is safe to say, however, that where busy intersections cross bridge approaches, a roadway width greater than that of the bridge proper is justified, and finally that there is need for more study and observation on this whole question of maximum capacity of roadways for motor traffic.

To The New President

IN ACCORDANCE with precedent President Coolidge has announced his intention to carry out in full the policies of his predecessor. There is no doubt of the honesty of this intention but history has shown that each of our Presidents who succeeded in like fashion has before long been forced by the strength of his own convictions and by the force of his own personality into policies of his own, which quite possibly may be in opposition to those which he inherited. Engineers and contractors who have watched as professional and business men and not as partisans the course of the Harding administration, could they obtain the ear of Mr. Coolidge, might well point out some definite viewpoints as to past and future performances which might be of value to the new President.

In the first place there would be praise for the fiscal policy of the Harding administration. In these days of foreign and domestic complications too little credit has been given for the planning at Washington which has led to that combination of increasing income and decreasing outgo which is the primary requirement for either business or government. The excellent administration of the Treasury, which has so successfully taken care of the early stages of the retirement of the war bonds, the successful adjustment of the British debt, the initiation and execution of the beginnings of the federal budget, the veto of the soldiers' bonus with the terrific added burden of expense which was thereby prevented, and the reduction in costly armament (itself possibly the minor part of that crowning diplomatic triumph, the Washington conference, the Far-Eastern agreement and the four-power treaty)—all go to make up a consistently economical fiscal plan for which the administration deserves more praise than has usually been given. Add to this the sane attitude toward

business, best exemplified in the methods of the engineer member of the cabinet, and we have a purposeful policy carried out, insofar as it has gone, to the benefit of the country. Few engineers will be found who would advise the President to depart from the course laid out in these matters.

There are, however, two acts, or series of acts, of the Harding administration which in the mind of the engineering profession have been manifestly improper. To what degree the late President approved or condoned them we do not know. We do know, though, that a new chief executive, however much he may feel bound to his late chief, will do well to consider their inherent justice as well as their effect on his political fortunes. We refer to the violent campaign carried on by Attorney General Daugherty against the engineers and contractors of the army construction program and to the reorganization—and possibly disorganization—of the Reclamation Service begun by Secretary of the Interior Work by the dismissal of Director Arthur P. Davis.

Both of these performances smell too strong of party politics. The whole history of the Construction Division suits and indictments, from the strictly partisan Congressional investigation to the personnel of the staff which is using that investigation as its bible, brand that persecution with political motives. It was plainly an effort to magnify the new administration by discrediting the Wilson administration. Reputable engineers and contractors were to be made martyrs in the process. A new and independent study of these cases by the President should be made. He is the one who will now suffer if they are pursued to their apparently inevitably unsuccessful conclusion.

The Reclamation Service case is too fresh in the minds of engineers to need description. Suffice it to say that the evidence is accumulating that Secretary Work was governed more by the necessity for providing a place for one who is politically powerful in certain sections of the West where votes are needed than in an honest effort to put reclamation on a sound basis. Governor Davis, the new commissioner of reclamation, has a business past which is anything but a recommendation if the avowed "business administration" is the main thing being sought in the Reclamation Bureau, but he has been twice elected governor of Idaho and is wise in political methods. The trip to Alaska and the tragedy at San Francisco will delay for a while the combined efforts of the engineers of the country to defend the engineering control of irrigation but nevertheless the evidence in the case is being accumulated and when Congress comes to meet in November, the Secretary will find that he has opened up a controversy which is far wider in its implications than perhaps even he realized. Here again the new President is free to take his own course and to refuse to be burdened by the unwisdom of his predecessors.

Engineers have no desire to form a professional soviet which thinks and acts only for the good of the profession. They are, however, by virtue of their vocation closely concerned with public activities and vitally interested in public policies. We believe, furthermore, that engineering is essentially an unselfish profession, perhaps too unselfish for its own good, but certainly one that is looking toward benefiting the general run of the people all the time. For that reason the views of engineers on such public questions as these are, we submit, worthy of consideration.

Structural Engineering in Dirigible Airship Work:

Building the Navy Airship ZR1

Completion of Ship Marks
Solution of Complex Problems of Structural Design.
Related to Those Worked Out in Development of Bridge and Building Work

FIG. 1—ZR1 APPROACHING COMPLETION

Strength of Riveted Duralumin Members Determined by Tests and Problems of Fabrication and Assembly Worked Out by Trial in the Shop—Elaborate Test Work

IN UNDERTAKING to build its first rigid airship, the ZR1, the U. S. Navy Department confronted a complex mass of new problems. The completion of the ship, now ready for its trial flights, marks the successful solution of these problems. They are essentially problems of structural design and fabrication, and are closely related to those which have been worked out by gradual practical development in the related field of steel structural work for building and bridge construction.

The ZR1 is a huge structural framework of latticed struts braced by wire ties. Though precisely similar to any structural steel frame in its principles of arrange-

ment, it is made radically different from such a frame by three characteristics: (1) The metal is duralumin, a light alloy of aluminum and copper; (2) the material is in sheet metal thicknesses; (3) the members, with few exceptions, are of triangular cross-section, so that the joints become special problems involving great complication.

The peculiarities of the duralumin, the problems of fabricating and assembling the sheet metal members, and the difficulties presented by the joints and of connections constituted the outstanding elements of the fabrication problem.

FIG. 2—GENERAL DRAWING OF THE U. S. NAVY DIRIGIBLE AIRSHIP ZR1, BUILT AT LAKEHURST NAVAL AIR STATION

Design presented equal complications and difficulties, in view of the commanding importance of weight economy and on the other hand the absence of precise data for estimation of attacking forces and analysis of the resisting strength of the frame. This part of the development, however, may be summarized for present purposes by the statement that the design is modeled closely after the most successful foreign practice but that many members and parts were increased in strength. Careful analyses of the stresses in the frame for the estimated loads, wind pressures and accelerations were made by two methods of approximate solution of

Department. The detailed findings of this board have not been made public, but they are known to include a complete endorsement of the design as safe and adequate.

Structure and Material—For a general understanding of the construction problem it is necessary to outline a few essential facts concerning the structure of the ship and the material used. The frame of the ship, a cigar-shaped body of circular cross-section, 680 ft. long and 79 ft. (24 m.) in diameter in the mid-section, is made up of frame rings spaced 32.8 ft. apart, connected by thirteen longitudinals and made rigid by diagonal

FIGS. 3 AND 4—DURALUMIN FRAMEWORK AND AN INTERIOR JOINT OF THE FRAME

the complex indeterminate framework, which two methods represent opposite divergences from the true condition and thus yield opposite limiting values of the frame stresses. An independent reinvestigation of the design was made last year by an engineering board appointed by the department, composed of men outside the Navy

wire bracing in the transverse planes of the frames and in the rectangular panels formed by frame members and longitudinals. Halfway between the main frames are intermediate frames, of lighter section and without transverse wire bracing; similarly, halfway between the main longitudinals are intermediate longitudinals, this

Feet

secondary system being braced by a system of secondary wire diagonals in the outer surface. The entire hull frame weighs only about 15 tons; as there are about 3,000 struts in the frame, this is less than 10 lb. weight per average strut. Duralumin, the material used, has a specific gravity of 2.8 (slightly more than one-third that of steel), an ultimate strength of about 55,000 lb. per square inch and a minimum yield point of about 35,000. The frame members are essentially struts or columns, and stiffness against buckling required that

fabrication, chiefly due to the very light thicknesses of the shapes used. These may be readily appreciated by comparing with ordinary structural steel. As in any structural framework, it was vital that the individual members should be straight and that the structure should be assembled firmly and true to form, with bracing of uniform tension.

Fabrication of the latticed struts was the first and principal problem.

Fabrication of Struts—Duralumin rolled channels of

SPECIAL TOOLS FOR DRILLING AND RIVETING STRUTS

they be of large transverse dimensions and hence of very small metal thickness. For weight economy they were made of triangular cross-section.

Metallurgical difficulties in the production, rolling and handling of duralumin have been largely overcome. The metal may be annealed to a soft state by heating for one-half to one hour at 350 deg. C., and either quenching or slow cooling; or it may be brought to a tempered condition by heating to 490 deg. C. and cooling. Immediately after the tempering treatment it is soft, and remains so for one or two hours, slowly assuming the hard condition. The hard condition is wanted in the finished structural members, but work must be done in the soft condition. The processes of manufacture must therefore be arranged to utilize the short-time soft state immediately following the tempering treatment, unless tempering of the finished article is practicable.

Aside from the difficulties introduced by the nature of the material, there were perplexing difficulties of

special section for the main members of the struts, and stamped and punched lattice bars were furnished from the mill of the Aluminum Co. of America. The channels were in random lengths, to be cut to length at the factory as required. The lattice bars, cut and formed by die stamping from an annealed rolled strip and punched for the end and center connection rivets, were received ready for assembly.

Fabrication of the parts of the airship was allocated to the League Island Navy Yard, Philadelphia, and erection of the airship to the newly built naval air station at Lakehurst, N. J., where an airship shed 264 x 803 ft. was built three years ago for constructing and housing dirigible balloons (see *Engineering News-Record*, May 6, 1920, p. 892). The work was put in charge of Commander R. D. Weyerbacher, U. S. N., who organized the fabrication at League Island and later took up the erection work at Lakehurst. In both parts of the work it was necessary to develop methods, tools and machines from the ground up, and work out in

succession the problems met in the work. In spite of the assistance of English and German airship experts, the work remained essentially a pioneer undertaking.

Assembling Lattice Bars—For quicker and more accurate assembly of the struts the lattice bars were first riveted together in pairs to form crosses. The necessary high precision was obtained by use of a two-piece fixture shown in Fig. 5. A rectangular plate with corner dowels receives the two lattice bars and positions them; when it is laid over a die plate having three dowels registering with holes in the rectangular plate, the four central rivet holes are brought directly over rivet dies on the die plate, and all four rivets are headed up in one stroke of the press in which the die plate is mounted. The punching of the lattice bars is initially checked up by their fit on the dowels of the frame plate; absence of distortion in the course of the riveting is checked by noting the absence of binding when the riveted cross is removed from and replaced on the plate.

Drilling the Channels—The channels which form the longitudinal members of the struts are first cut to length by hand hack saws, allowing 2-in. over-run at each end. The rivet holes are then drilled in an automatic spacing machine (Fig. 6).

The triangular struts, which form the entire framework except for a few rectangular struts in minor positions, are of two shapes, equilateral and isosceles, the latter having a long side equal to twice the short side. Two forms of channel were provided, differing in the angle between the flanges. Both sections are 1.18 in. wide on the back and 0.459 in. wide on the flange, with the outer edge of the flange slightly turned in to stiffen it; they are 0.59 in. deep. Their thickness ranges from 0.031 to 0.079 in. The angle between flanges is 60 deg. for the channels used in the equilateral sections and the base channels of the isosceles section, and about 45 deg. for the channel used at the peak of the isosceles struts.

In foreign practice, the struts have been built up complete in box-like forms, in which the channels and lattice bars were held firmly in position and then drilled and riveted in place. The builders of the ZR1 decided upon pre-fabrication as being more rapid and accurate, believing that precision in locating the rivet holes would assure straightness and truth of the struts. Laying out and individual drilling of the holes were out of the question from this standpoint, and the development of an automatic mechanical spacing machine was undertaken, with entire success. This is the machine shown in Fig. 6.

One end of the channel to be drilled is attached to a light carriage pulled along the table of this machine by a weight. Dogs along the sides of the table bring

FIG. 8—A TYPICAL FRAME JOINT

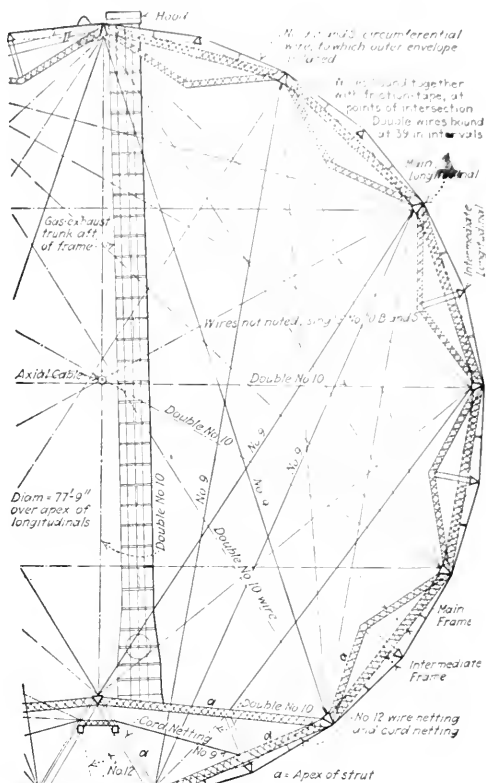

FIG. 9—FRAMEWORK OF ZR1 IN TRANSVERSE SECTION

the carriage to a stop at the proper position for a rivet hole. As the table strikes the dog, it trips a clutch which actuates a cam shaft (on a stand on the floor beside the machine) by means of which four control motions are initiated in succession. The first presses a hold-down pad on the channel at the point of drilling, the second closes the drill circuit, the third feeds and returns the drill, and the fourth throws out the dog and sets the following one.

A high degree of precision is required in the work. An accumulated error of 0.006 in. on the 18-ft. length of a strut gives the finished strut a wind of $\frac{1}{4}$ in. in a 5-m. length. It was therefore considered necessary to limit the overall error in rivet holes in one channel to 0.002 in. To assure this degree of precision the stops on the machine were set up by the use of fixed end-gages corresponding to the various rivet spacings required.

With the channels drilled thus accurately and the lattice crosses assembled precisely by help of the fixture plate previously described, it is possible to assemble a strut in the open and obtain entirely satisfactory results. Quicker work can be done, however, by assembling it in a form. Such forms, as shown in Fig. 10, have therefore been used for most of the work. Before the parts of the strut are placed in the form, the peak channel is clamped, back down, on a base strip and the lattices of both sides are bolted to it, with bolts in half the total number of holes; the bolts are set up tight by screw-

driver. Similarly the two base channels are bolted to the bottom lattice, on a flat support. The two parts then go into the form, where the strut is assembled peak down and clamped. The empty holes are riveted and then the bolts are successively replaced by rivets.

Rivets are driven cold. The air-operated toggle riveting press (Fig. 7) is also one of the tools designed for the job. It has a 3-in. air cylinder, and with 85 lb. air exerts a pressure of about 3,000 lb. It is necessary to adjust the grip of this press (gap at full stroke) to the grip of the rivet to be driven, as greater closure would be likely to deform or cut the metal of the channel; this adjustment is made by changing the dies, various dies of suitable length being provided. The strut shown in Fig. 7 happens to be of square section, through the main framing of the dirigible consists of triangular struts.

FIGS. 10 AND 11—ASSEMBLING STRUT SECTIONS IN FORMS AND A GROUP OF HAND RIVETING TOOLS

Doubled latticing (successive lattice crosses half spaced) is provided at the ends and load points of those struts which have to carry transverse load, as occurs in a number of members in the keel section, and also in general where strength of joint is important. For the necessary inside attachment of alternate lattice members the in-turned edge of the channel flange must be straightened. This "lipping out" is done by a small press, or in individual cases by a hand tool shaped like a broad flat-nosed pliers (shown in Fig. 11). Lipping out tends to curve a channel concave toward its inner edge, but the operator can neutralize this tendency by bending the channel out during the operation.

Riveting—Three sizes of rivets are used in the structure, 0.0965 in. for the center connections of the lattice bars, 0.115 in. for the girder-lattice connections, and 0.154 in. for the joints. They are tempered before driving and must be driven within an hour following this treatment. In fabrication as well as erection the system was followed of collecting all undriven rivets at one-hour intervals and distributing freshly treated rivets.

Joint Detailing—Details of typical connections were worked out on the drawing board in the course of the original design, but much of the detailing was left to the shop, to be worked out in actual set-up. No attempt was made to develop templets or shape the connection parts from the drawings, but all these data were worked out by shop set-ups or, as they were called, "mockups." Where a large number of duplicate joints was involved, all or part of the mockup was built with waste members

or ends of members, and the details worked out with them thereafter were used as templets for laying out the total number of connection pieces required. Where only one connection of a given kind was to be made, it was usually worked out on the members themselves.

If the complexity of the joints involved in the airship structure is considered, it may be realized that the detailing of the joints was a very tedious and extensive item of the whole work. A number of joints may be seen among the accompanying views, and two mockups are shown. In the original drilling of the channels on the spacing table, the connections were in all cases left blank, and they were drilled later in the mockup or from the templet produced thereby.

A special method of working out the joints was applied to the circumferential frames, which constitute the major part of the ship framing. A large floor jig

was built for fitting up these frames at League Island, as shown in Fig. 14. Thirteen radial members, passing through the peak point of the frame, carry movable support plates, on which are mounted vertical angle plates in the line of the two adjoining circumferential members. The plates are set at the proper distance out for a given frame, and then the frame members are laid in position against the angle plate, marked for bevel, cut, and the joint details worked out. On this jig, finally, the connection plates were riveted to one of the two connected frame members and bolted to the other, the frame being subsequently disassembled and the individual sections shipped to Lakehurst for re-erection on a similar jig and final riveting and wiring.

Several sub-assembly operations preceded and served this main assembly of the frame. Separate jigs were provided for these operations. On one the king post at mid-length of each main frame member was cut to bevel; on another the ends of the trussing struts of the king post frame were mitered, and on the third the trussed member was fully assembled. Connection plates and parts worked out from templets were also bent, cut and drilled in sub-assembly shops.

The main frame jig at League Island was adjustable for all frames, main and intermediate (the latter are 25-sided polygons in place of 13-sided as are the main frames, and their members are not trussed). After the early stages, however, to speed the work the intermediate frames were beveled and detailed by templet and were assembled on a loft floor, leaving the jig free for work on the main frames.

FIG. 19—SERVED AND SOLDERED BRACE-WIRE LOOP

All completed members were varnished by compressed air spray (Fig. 13), using clear varnish with a small amount of blue pigment. Most of the material was shipped from League Island to Lakehurst by motor truck.

Final Assembly—A floor jig like that used at League Island but somewhat simpler in construction was built at Lakehurst for final assembly of the ring frames. Here they were riveted and the diametral and chord wiring which holds the ring to shape was inserted and drawn up to proper tension. With some care in han-

dling, the completed frame could be picked up without serious distortion and handled by hoist lines suspended from the roof, over to the erection trestles, along one side of the big hangar, where it was set and blocked up, being lined up transversely and longitudinally by transit to true position.

FIG. 20—CENTRAL SECTION ERECTED AND BRACED

dling, the completed frame could be picked up without serious distortion and handled by hoist lines suspended from the roof, over to the erection trestles, along one side of the big hangar, where it was set and blocked up, being lined up transversely and longitudinally by transit to true position.

Erection—The system of erection differed from that used in England, where it has been customary to set and brace permanently a pair of frames, then skip a panel and erect and brace the next pair of frames, later filling in the empty panels. For the Lakehurst work it was decided that continuous working would be better, starting from a rigid mid-section to be first set and braced. Accordingly the middle six frames were set, the longitudinals put in place, beginning at the bottom, first in the middle panel and then in the panels to either side, etc., and finally the wire bracing between frames and longitudinals was put in in similar sequence. In this process the farthest advanced portion, at the middle, was at all times more rigid than the portions to either side, and disturbance or distortion was minimized by carrying on the work symmetrically toward either end of the group of frames. It was thus possible without great difficulty to maintain the framework true and thus finally produce a mid-section fully braced and true to form, with uniform tensions in the bracing wires. In this initial operation only the main frames and longi-

tudinals were placed, and the secondary system with its secondary bracing followed as a second operation.

Once the rigid central section was complete, work could progress toward either end independently without any tendency to distortion.

Inserting the Brace Wiring—The wire bracing throughout the ship consists of hard drawn steel wire from No. 9 to No. 11 wire gage, with No. 12 and No. 13 used in some minor services. Turnbuckles are not used, but instead the wire is drawn up and end loops formed and safe-ended, with the use of a tensioning device which permits the application of precisely the tension wanted. The tensioning device consists of a small winding frame comprising a cable drum or spindle attached to a gear, and a crank handle attached to a pinion meshing with the gear; a pawl on the housing of the device engages a ratchet wheel on the pinion shaft. A vise-like clamp is connected by a link to the winding gear housing, and a similar one is attached to the outer end of a length of tiller rope which is wound on the drum of the winding gear. When a wire diagonal is to be put in, one end of the wire is passed through one of the eyes which it is to connect, a loop is bent, served with wire wrapping and soldered; then the other end of the wire is passed through its eye, and one of the clamps of the pulling device is attached to this free end, while the other clamp is attached to the standing part of the wire near the opposite eye. By means of the ratchet gear the connecting rope is wound up on the drum and the free end of the wire thereby pulled up to any desired tension. The tension in the standing part of the wire is measured with a Larson wire-tension gage while the pulling goes on, and when it reaches 300-lb. tension, the desired amount in the diagonals of this airship, the free end of the wire is clamped to the standing part, served and soldered. The serving is done with No. 30 annealed steel wire, put on in about 100 turns with a small space left every fifth turn. Without releasing the

FIG. 21—ERECTION PROGRESSING TOWARD TAIL

clamp, the serving is then filled with a flux of stearic acid and resin, and soldered and wiped. The result is shown in Fig. 19.

Fitting Longitudinals—The field connections of longitudinals to the ring frame were drilled in the field; the end details were worked out fully in the League Island factory, and cut and formed, but the rivet holes were drilled in the member from the connecting holes in

frames and gusset plates when the longitudinal was actually built into the ship on the blocks.

Protection Netting and Skin—Each longitudinal element of the ship between main frames (10 m. long) is

FIG. 22—GASOLINE TANKS HUNG ALONG KEEL PASSAGEWAY

occupied by a separate gas bag. The bag has a manually operated escape valve at the top and an automatic release valve at the bottom, vented upward through a tube passing between the bags. To resist the bulging tendency of the bags in the openings between the frame members, the entire inner surface of the frame is covered with a tightly stretched network of crossed diagonal wires (No. 13) spaced about 18 in., which are fastened to the inner channels of the longitudinals and ring frames. Inside of these is a smaller netting of knotted ramie cord, about 9 in. mesh.

A skin of impregnated fabric covers the outside of the ship. It is put on in wide longitudinal strips, which are laced to the frame members around their edges. The spaces between the sections of fabric are covered with strips cemented on, and the entire skin is brush-coated with cellulose acetate.

Tests to Be Made—Wind and air resistance forces are applied to the airship structure through this skin. Buoyancy forces are applied by the retaining wire mesh-work surrounding the gas bag, and bear chiefly on the frame members about mid-height of the structure. Loads other than the hull weight itself are due to the cars (power and control), fuel tanks hung along the sides of the keel passageway, and water ballast bags of one ton each in the same location. These vertical forces are applied partly at six panel points of the ring frames in the lower quarter, and partly along the length of intermediate longitudinals in the upper part of the keel section. The propulsive forces are exerted at the frame panel points to which the center and side power cars are fastened. Certain concentrated forces due to the action of the fins and rudder surfaces act on the tail section.

With the forces of attack on the structure thus concentrated at different points of the ship, knowledge of the way in which stresses distribute through the structure is of great importance. The difficulties of analysis in view of the very high degree of static indeterminacy of the structure are, however, such that theoretical knowledge of the stress distribution is quite imperfect.

On this account it is planned to make elaborate tests when the ship is completed. By comparison of the results of the stress measurement in these tests with calculation results, a high degree of approximation in correcting the theory is attainable.

Certain of the tests have already been made. One of them is illustrated in Fig. 24, showing one of the gas bags inflated, putting tension on the transverse wiring of the main frames at either end and correspondingly putting the frame itself in compression. Several thousand stress and distortion measurements were made in this test, or rather in a subsequent test of which this was the preliminary. For accurate measurement of distortions a wooden bridge, 85 ft. in span and 110 ft. high, was built over the test panel (Fig. 23) before the final gas-bag test was made. The results of the test agreed closely with calculations of ring stresses, as

FIG. 23—BRIDGE OVER CENTRAL PART OF SHIP FOR GAS-BAG TEST; SPAN 85 FT., HEIGHT 110 FT.

might be expected if the structure was of reasonably uniform constitution.

In the tests after completion of the ship more significant results are likely to be obtained. These tests will be made under full buoyancy, with loads applied at definite positions along the keel and then shifted to other positions, giving a known change in bending moment. Comparison of the stresses measured for the two positions will give precise values of the stresses due to the increase or decrease in bending moment.

Local tests are being made on different parts of the structure. The tail stresses due to pressures on the fins are being investigated by measurement under known loads placed on the fins. It is probable also that tests in flight will be carried out. The McCollum-Peters carbon-resistance strain-gages of the Bureau of Standards (*Engineering News-Record*, July 5, 1923, p. 27) are used for the stress measurements. These gages permit making stress measurements at points inaccessible during the measurements and enable the readings from a large number of points to be taken at one central point.

Mechanical Problems—The various problems encountered in the equipment of the ship cannot be gone into here. One of them may be noted, however, to illustrate the original experimentation required in their solution.

The aluminum gasoline distributing piping in the ship is connected by fittings of sand-cast "linite," an

aluminum alloy. These fittings proved to be very porous; practically the entire lot leaked gasoline under a pressure test. The problem was to make them tight. Extensive experiments were carried out. Finally, success was attained by impregnating the castings with silicate of soda (water glass) under pressure. In the method finally used a lot of the castings are first subjected to a vacuum (25½ in. mercury was obtained), after which the water glass solution is admitted. The tank full of castings immersed in the solution is then subjected to a pressure of 300 lb. per square inch, which is left on for an hour. When taken out of the solution the castings are dried in the sun or at a gentle heat. The treatment makes them tight against gasoline in

sign, fabrication of parts of the structure and power plant installation were performed at the Naval Aircraft Factory, Navy Yard, Philadelphia, Pa., under the direction of Commander G. C. Westervelt, Construction Corps, U. S. Navy, its manager. The development of plant facilities, methods and processes of erection and tests of the ZR1 were performed under the direction of Commander R. D. Weyerbacher, Construction Corps, U. S. Navy, manager, Naval Air Station, Lakehurst, N. J.

Truck Sizes and Traffic Capacity of Highways

Extract from an address by Major F. S. Besson, Assistant Engineer Commissioner, District of Columbia, before the Washington Society of Automotive Engineers.

IN ORDER that the maximum capacity of highways may be developed, the widths of vehicles, with their loads, must be limited to 7½ ft. Likewise, in order to obtain this maximum capacity it would appear to be unwise to eliminate the 7½-ton truck, for its load would then be carried by more than one truck and more space would be occupied on the roadway.

A 7½-ton truck weighs, on the average, 11,000 lb. with no load, and 27,000 lb. loaded. Its average length over all is 21 ft. If its load is carried on 1½-ton trucks, five are necessary, the total weight of which unloaded would be 25,000 lb. compared to 11,000 lb. for the 7½-ton truck; and the length over all on the road would be 135 ft. compared to 21 ft. for the 7½-ton truck. Furthermore, we are not certain as yet, granted that the two types of trucks are equally well designed, that carrying the load on 20 wheels would not do more damage to the pavement than carrying it on 4 wheels. Certainly congestion on the streets would be greatly increased. Gross weight alone is not the all-important factor. Speed, unsprung weight, wheel loads, character of tires, tractive stress on the pavement, all these enter into the matter.

Pavements can be built at reasonable cost strong enough to carry 7½-ton trucks. Practically every pavement failure in Washington has been examined and in no case could blame be placed upon the heavy truck. Engineers need some unit upon which to base design and, having adopted the 7½-ton truck as this unit, the public should be informed that this limit is to continue indefinitely.

Within the permissible gross weights for vehicles, certain regulation is, however, required. A basic rule should be that trucks may not carry more than the weight for which they are manufactured, and in accordance with which weights the owners have paid fees in obtaining operating permits. The motor vehicle industry condemns overloading, and manufacturers generally are arriving at the point where they furnish caution plates stamped with chassis and body weights and load capacities. In accordance with the data furnished by the manufacturers, the license bureau should make certain that the permissible gross weights are painted on the sides of all cargo vehicles, and fees should conform to these gross weights.

It is believed fair to base registration fees for the time being on maximum gross weight alone, at 50c. per hundred pounds. Passengers should be rated at 150 lb. each. Thus, the usual 5-passenger car, weighing loaded about 3,200 lb., loaded would pay a fee of \$16; a Ford roadster about \$10; a heavy limousine probably \$30; a 7½-ton truck, gross weight about 28,000 lb., \$140.

These fees equal about the average paid throughout the United States, when gasoline, personal, and all other taxes combined are considered. The main principle of the suggested rate is that vehicles are taxed upon a graduated scale. It may not be absolutely accurate as judged from the pavement standpoint, but it is as nearly so as can be made under the present state of our knowledge. An important point is to enforce loading regulations.

FIG. 24—GAS-BAG TEST OF TRANSVERSE WIRING AND FRAME RINGS

tests at 110 lb. pressure, which is several times as great as the highest service pressure.

It may be added that expansion is provided for in the longitudinal piping as well as in the wire and wire-rope lines of the control system, which operates valves of gas bags, ballast tanks, and the like, engine telegraphs, rudders and other necessary controls throughout the ship from the control car under the forward portion of the keel. The expansion provision in the pipes consists of goosenecks, while the wire and cable lines have mechanical take-up, also operated from the control car.

The general design of the Fleet Airship ZR1 was started under the direction of Commander J. C. Hunsaker, Construction Corps, U. S. Navy. The design of airships was under the cognizance of the Bureau of Construction and Repair. As chief of the bureau of construction and repair, Rear Admiral D. W. Taylor always displayed great interest in airships and due to his energy the work never lagged. Upon formation of the Bureau of Aeronautics, under Rear Admiral W. A. Moffett, the design of the ZR1 was completed under the direction of Commander Hunsaker. The detailed de-

New Gravity Freight Yard at Denison, Tex.; M.-K.-T. Ry.

**Extensive Layout on Cutoff Line Has Daily Capacity for 80 Trains and Classifying 2,000 Cars—
Two Hump Tracks Have Different Grades—Separate Departure Yards**

OF MANY projects on the extensive improvement program which has been carried out during the receivership or the Missouri-Kansas-Texas Lines, the largest single undertaking is the new freight terminal at Denison, Tex., which it is expected to have complete and ready for service in August, 1923. Heavy concentration of traffic occurs at this place and the layout includes units for southbound and northbound movements. Each unit has a receiving yard and a combined classification and departure yard, these two yards being connected by a hump track. A special feature of the design is that provision is made for future development of a separate departure yard in each unit, to be located beyond the

Studies showed that present traffic conditions require a yard of sufficient capacity to handle about forty inbound and forty outbound trains per 24 hours, and to switch and classify approximately 1,500 to 2,000 cars in the same period. Furthermore, the volume of traffic is increasing steadily and provision for growth was a prime requisite in the design of the new terminal.

Yard Layout—From the plan, Fig. 2, it will be seen that the northbound and southbound units are parallel with each other and that the two parts of each unit are in tandem, connected by the hump track. In the northbound unit the capacity of the receiving tracks is 60 to 92 cars and that of the classification tracks is 51 to 145 cars. In the southbound unit the receiving tracks hold from 86 to 121 cars and the classification tracks from 71 to 87 cars. The body tracks are spaced 13 ft. c. to c., and 16 to 18 ft. c. to c. from running tracks. Yard ladders have No. 8 frogs with a lead angle of 8 deg. 34 min. and a spacing of 84 ft. between points of switches. Turnouts from lead tracks also have No. 8 frogs. Rails of different weights are used at present, all laid on crossties, with gravel and sand ballast for yard tracks and stone ballast on the connection to the main line. Drainage is provided by culverts crossing the yards, some of these being reinforced-concrete boxes 8 x 6 ft. with inlets 20 x 24 in. between the tracks.

Two caboose tracks holding 22 cabooses in all and a 12-car bad-order or cripple track are located alongside the upper or rear end of each classification yard, so as to be served by a minimum amount of switching. These tracks are 16 ft. c. to c. Between the two units and readily accessible from them are a car repair yard and a transfer platform for handling L.C.L. freight. South of the yard is the engine terminal, approached by running tracks from both directions. Yard tracks now under construction aggregate sixty miles and are divided as shown in Table I.

FIG. 1—NEW AND OLD FREIGHT TERMINALS AT DENISON, TEX.; M.-K.-T. RY.

classification yard. The general situation is shown in Fig. 1.

For some years past the old yard, built in 1894 and enlarged in 1909, has been inadequate for the traffic and the amount of classification required. In planning the improvement, consideration was given first to the expansion of the old facilities, but this would have required heavy grading and unfavorable alignment involving inconvenient and expensive operating conditions.

A new location was selected therefore about a mile from the old yard and requiring a new approach line. This site is much more favorable as to grades and curvature and is well adapted to a hump yard layout, since it has open rolling ground which descends with moderate slopes in both directions from a central ridge and is intersected by ravines which provide excellent lateral drainage. The axis of the yard is a tangent for more than a mile in each direction from the hump and the natural fall of the ground is favorable to the hump profile. In the six miles of new work, including a three-mile single track connecting to the main line at the south end, the length of freight main track is shortened by 1.3 miles, with a reduction of 235 deg. of central angle in total curvature and 72 ft. in rise and fall. This new work being entirely separate from the old facilities, its construction involves no interference with traffic and no disturbance of existing tracks. The new six-mile freight line leaves the Warner cutoff west of M.P. 660 (see Fig. 1) and joins the main line near M.P. 669, just each of Pottsville.

Traffic Conditions—In the M.-K.-T. Ry. System, Denison is an important assembling and classification point.

TABLE I—TRACK CAPACITY OF DENISON FREIGHT TERMINAL

Yard	Number of Tracks	Standing Car Capacity		
		Maximum	Minimum	Total
Southbound receiving	6	121	88	600
Southbound classification	16	87	3	1,200
Northbound receiving	10	92	69	700
Northbound classification	24	145	34	1,800
Car repair	4	17	14	63
L.C.L. transfer	4	18	18	75
Total				4,400

Interlocking plants protect the junctions of the new connecting line with the main line at Red River (Denison) and Pottsville. An automatic switch set for southbound movements but opening under northbound trains (and returning to normal position) connects the northbound and southbound sections of the yard with the single track connection at the north end, near M.P. 660 (Fig. 1).

There are no highway crossings at grade within the yard limits. Two highways, one near the north end of the yard and one at the hump, are carried over the tracks on steel spans. One highway at the south end of the yard passes under the yard approach and switching lead through a concrete subway. Another over-crossing of timber trestle construction carries the main highway

FIG. 2—LAYOUT OF FREIGHT YARDS AT DENISON, TEX.

over the single-track freight main line which connects the south end of the yard with the Fort Worth division of the main line, five miles west of Denison.

Switching Humps—The two humps are nearly opposite each other and about 600 ft. apart, each with a 56-ft. 75-ton track scale conforming to the specifications of the U. S. Bureau of Standards. Their profiles are as shown in Fig. 3 and in Table II, the slightly steeper grade of the northbound hump being due to the larger proportion of empty cars in that direction. In each yard a track is provided for the operation of motor cars to return the car riders to the hump. In the southbound yard this track is located at the side of the body tracks but in the northbound yard it is located in the center, crossing under the classification lead through a concrete subway.

A considerable proportion of the traffic terminates or originates in Denison or on branch lines centering there. As this traffic comes from or is destined for points both north and south on the main line there is a certain amount of reverse movement of such cars. To meet this condition provision is made for convenient cross movements of cars over either hump, without separate switching, into tracks so located that cars can be classified in reverse direction over the other hump. It is expected that when traffic is light both humps will be operated by a single engine.

To control the movements of the hump engines, electrical signals, operated from the humps, are placed on the steel spans which carry the highway over the hump tracks. The switches of the classification tracks are thrown by hand.

Miscellaneous Yard Facilities — Transfer for L.C.L. freight in order to consolidate shipments is provided for by a timber platform 24 x 600 ft. having an office and locker room. This platform, Fig. 4, serves two tracks 12 ft. c. to c. on each side. Creosoted pile butts on concrete footings carry joists 10 ft. apart on which are stringers for the 2½-in. floor planking. Along each side of the platform a trucking runway is formed by a pair of 10-in. steel plates ½ in. thick, the floor being grooved so that these plates are flush with the surface. Two-post bents 20 ft. apart carry stringers for the joists of the butterfly roof. By inclosing three bays of these bents, an office 10 x 60 ft. is formed and the lighting and ventilation of this inclosure is assisted by a triangular skylight with hinged sash, as shown.

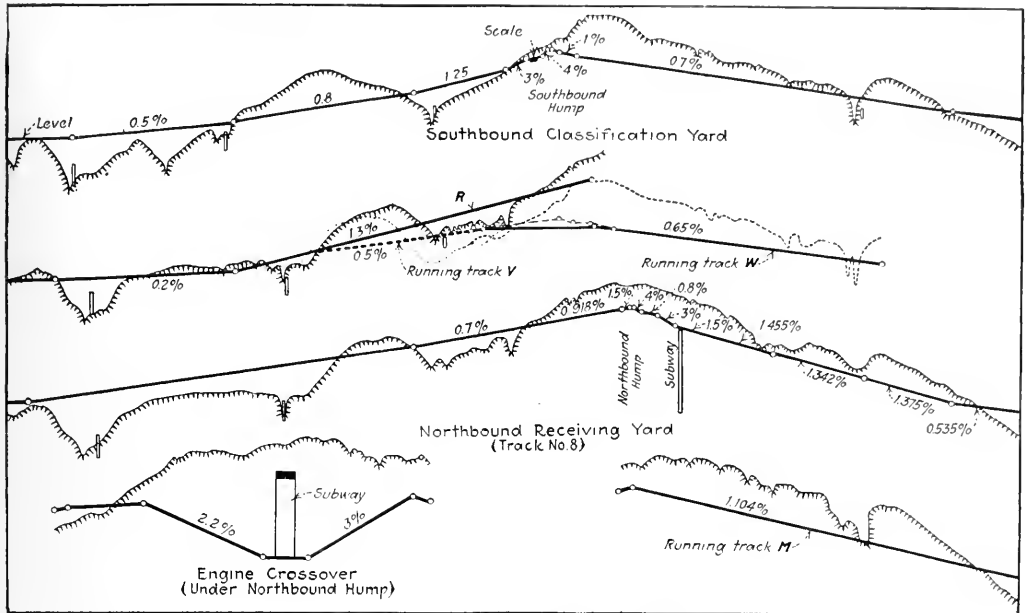

FIG. 3.—PROFILES OF SWITCHING HUMPS

An icing station along the north side of the northbound receiving yard comprises a 100-ton ice storage house of frame construction, an ice crusher, conveyors and a double-deck platform 16 x 800 ft. for delivering block or crushed ice to the bunkers of refrigerator cars. This plant serves two tracks 29 ft. c. to c. Stock pens are provided for unloading and feeding stock in transit.

Car repair facilities are provided at four tracks spaced 16, 20 and 24 ft. c. to c., two of which are covered by a shed 200 x 40 ft. There are also a lumber shed, small shop, office and storeroom, served by a material track at the rear. Compressed air is piped from the power house to the repair tracks and also to the departure tracks for testing the train brakes. A two-

turntable. This turntable also serves twelve radial tracks opposite the roundhouse. All the radial tracks are at an angle of 5 deg. 48 min. 23 sec. The layout of the engine terminal is shown in Fig. 5.

Concrete engine pits 79 ft. long provide for inspection and repair in the roundhouse, Fig. 6. A drop pit for handling driving wheels and axles serves the three tracks which extend into the shop, and two of the other tracks are served by a smaller drop pit for truck wheels. Four post cranes are located adjacent to the larger drop pit. The roundhouse floor is of concrete. Wooden swinging doors form the inner front of the building, and the outer or rear wall has a large proportion of glazed area. In the middle of the roof of the roundhouse is a high and wide cupola or monitor, with ventilating sash.

The shop, of brick and steel construction, is divided into two parts by 50-ft. working pits in three of the roundhouse tracks which are extended into the shop. At one end of the shop are the machine tools and the other end is used for blacksmith and tube work. A 10-ton electric overhead crane travels the entire length of the shop and handles materials between the locomotives and the machines.

This shop building is connected also by a covered passage with the concrete and brick store and oil house, 60 x 120 ft. The floor of the store house and the adjoining platform are at the same elevation as the shop floor and the track serving them is depressed so that the car floor is level with the platforms. This arrangement of all facilities under one roof and at one floor level provides passage between roundhouse, shop and store house with a minimum of man-travel. Windows in the shop buildings and roundhouse have steel sash glazed with factory wire glass. The roundhouse cupola has wood sash. The roundhouse and shop are

TABLE II.—PROFILES OF SWITCHING HUMPS IN YARD AT DENISON, TEX.; M-K-T RY

story brick yard office is located midway between the humps, giving a good view of the entire yard and convenient access to the humps and the transfer platform.

Engine Terminal—The locomotive facilities, arranged at the south side of the yard, include a 100-ft. deck turntable of center-bearing type operated by an electric tractor, and a 22-stall brick and frame roundhouse 105 ft. deep with shop annex 72 x 225 ft. There is no through track, the roundhouse being served only by the

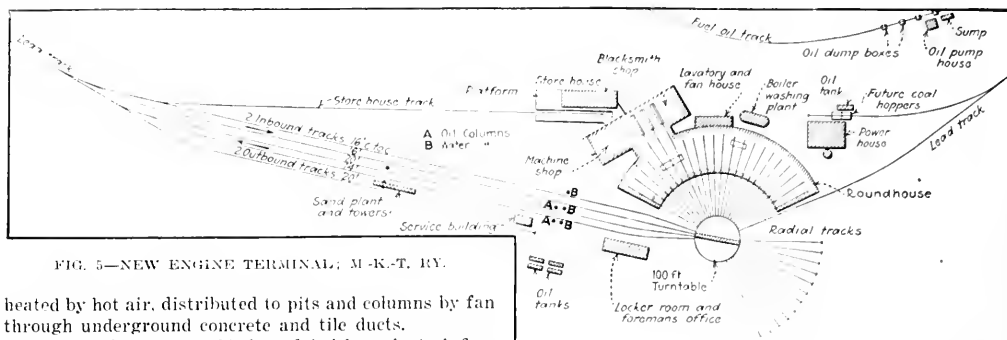

FIG. 5—NEW ENGINE TERMINAL: M.-K.-T. RY.

heated by hot air, distributed to pits and columns by fan through underground concrete and tile ducts.

A power house, 60 x 83 ft., of brick and steel fire-proof construction, houses two 328-hp. water-tube boilers, two steam-driven compressors each with a capacity of 1,000 cu. ft. per second, together with fire pumps and other accessories. Electric power for operating machinery and for lighting the yard is purchased from the local power company and the power house will not contain any prime movers for the present, steam being provided only for operation of the compressors, the heating plant and the boiler washing plant. The boilers use oil fuel, but the power house is designed to accommodate future coal and ash handling facilities. A lavatory and locker room and a fan room for the heating system adjoin the back of the roundhouse, and the boiler-washing plant is housed in a separate structure.

Fuel and Water Supply.—Oil fuel is used by all locomotives operating out of this terminal and is supplied to the tender tanks by two oil columns near the roundhouse. Fuel oil is dumped from tank cars at eight oil boxes (see *Engineering News-Record*, 1921, Aug. 4, p. 183, and Oct. 13, p. 618) and is stored in five 55,000-barrel steel tanks which are surrounded by low earth banks for fire protection. From storage, the oil is

pumped to four 10,000-gal. elevated horizontal delivery tanks, which serve the oil columns. There is a sand-house and drier and the plans provide for a future coaling station and ash handling facilities when these shall be required.

Water is purchased from the city and delivered through a 10-in. main to a steel tank 115 ft. in diameter

FIG. 6—SECTION OF ROUNDHOUSE

and 30 ft. high, of 2,300,000 gal. capacity, erected on a hill about 900 ft. south of the roundhouse and with its bottom about 75 ft. above rail level. This tank supplies emergency storage and direct pressure for delivery of water to the engines. An elevated steel tank of 40,000-gal. capacity, opposite the humps, provides a service supply in the buildings and also supplies two water columns located along running tracks adjacent to the humps.

Engineers and Contractors.—Grading for the yard and locomotive terminal involved about 800,000 cu. yd. Culverts and bridges comprise 7,850 cu. yd. of concrete. The grading and concrete work was performed by the C. R. Cummins Co., Cleveland, Ohio; and Bowie, Lydon & Co., Chicago, were general contractors for the building work. Three oil tanks and the water storage tank were constructed by the Chicago Bridge & Iron Works, Chicago, and two oil tanks by the United Iron Works, Kansas City, Mo.; fuel oil facilities and boiler washing plant, by the National Boiler Washing Co., Chicago; water and air pipe lines and stock pens, by T. H. Johnson, Sedalia, Mo. Tracks are being laid and ballasted, including the furnishing of sand ballast for yard tracks, by Zay Gardner, McAlester, Okla. The cost of the whole project will be about \$3,200,000.

This improvement was planned and is being carried out under the supervision of F. Ringer, chief engineer, Missouri-Kansas-Texas Ry., assisted by J. M. Metcalf, principal assistant engineer; with A. L. Sparks, architect, in charge of preparation of building plans, and A. Harvey, construction engineer, in charge of the work on the ground.

Hammer Rigged to Follow Pile Down Under Water

Lumber Saved and Submarine Sawing Minimized on Foundations for Brooklyn Edison Power Plant Construction

BY THE USE of a rig which makes possible the driving of wood piles with a standard steam hammer submerged in water 30 to 40 ft. deep foundations have been prepared for the large new power plant along the East River, at the foot of Hudson Ave., for the Brooklyn Edison Co., New York City. The outstanding feature of the scheme of submarine driving is the mounting of the hammer on a long timber spud equipped with a T-rail track and a sliding carriage which allows the hammer to move down under water with the pile head to grade. Thus the use of a follower frequently employed in submarine driving of this sort is dispensed with, the full force of the blow of the hammer is delivered direct to the top of the pile, the costly operation of sawing off piles to grade under water is largely eliminated and short lengths of pile can be used effectively with little or no waste of lumber.

The Brooklyn work involved the driving of piles in 11 cofferdams containing heavy timber cross-bracing which divides the cofferdams into groups of rectangular pockets. The bottom is composed of sand and gravel. The foundation requirements called for piles having a penetration of from 15 to 25 ft., spaced on about 2-ft. centers. With the submarine rig described below 3,000 piles have been driven in three of the cofferdams. In the other cofferdams long piles were driven and cut off with a saw as described in *Engineering News-Record* of March 22, p. 548.

Sliding Carriage for Hammer—To avoid the necessity of unwatering the cofferdams, which would have brought great pressure on the interlocking steel sheet piling of which they are formed, the plan of submarine pile driving was decided upon. For this work, a submarine rig was developed consisting of a McKiernan-Terry steam hammer weighing 6,600 lb. mounted on a sliding carriage which, in turn, engages a vertical T-rail track attached to a 12x12-in. timber spud about 55 ft. long. The sliding carriage consists of a steel channel to which Z-bars are riveted to engage the head of the T-rail and the sides of which are, in turn, engaged by a second pair of Z-bars riveted to the back of the hammer. There is a stop riveted to the top of channel carriage to prevent the hammer from being pulled out of its guides, a similar stop at the upper end of the spud to limit the upward movement of the carriage, and a toe-piece at the bottom of the carriage, consisting of a pair of steel straps drilled with holes large enough to receive large spikes. The function of this toe-piece, through which one spike is driven from each side into the wood pile, is to hold the lower end of the pile in position, prior to the operation of the driving, and to guide it in its descent.

Wooden piles with 12 to 14-in. butts are delivered on barges alongside a scow within reach of a locomotive crane from the boom of which the piledriving equipment is suspended by a two-part wire cable. The operations preliminary to actual driving consist in sawing the wood piles to the proper length (15-25 ft.) by hand and shoeing them with metal points. A chain hitch is then passed around the pile and it is snaked to position under the

hammer which is raised as high as the stops on the channel carriage and the spud will permit. The top of the pile is then fitted under the bell-bottom anvil block of the hammer, the foot of the pile is swung into the U-shaped opening formed by the sides of the toe-piece, and two spikes, one from each side, are driven part way into the pile through the holes in the toe-piece to hold the pile point in line. The spud is then accurately spotted by the derrick boom, brought to a vertical position and held there by guy lines. The hammer on its sliding carriage is lowered until the pile point strikes bottom; in this position the hammer is completely submerged, although the spud is long enough so that its top is well above water level.

The first few blows of the hammer force the pile

HAMMER CARRIED ON SPUD BY SLIDING CARRIAGE
Cross-section shows carriage and track details.

down through the toe-piece, turning up the spikes and disengaging their grip. The hammer then follows the pile down through the water along its sliding carriage until the top of the pile reaches grade. The exhaust steam is led to the surface through a rubber hose. The hammer and spud are raised and the operation is repeated.

The Hammer—The hammer is of the double-acting type, operated, in this case, by steam at a pressure of about 100 lb. per square inch. The hammer has overall dimensions of 20x20x87 in., a cylinder bore of 8½ in. and a stroke of 16 in. It weighs, with its base, 6,600 lb. and delivers 140 strokes per minute. The energy per stroke is 7,700 ft.-lb. This is a standard model of hammer, but for submarine work it is equipped with a hose connection to supply compressed air to the bottom cylinder to compensate for the water pressure when the hammer is submerged. This prevents water from entering the cylinder and interfering with the reciprocating movement of the ram.

With this rig the number of piles driven in water 30 to 40 ft. deep average about 30 in an 8-hour day. The driving crew consists of 8 men, distributed as follows: 4 on the guides; 2 sawing piles to proper length and attaching shoes; 1 on the hoist; and 1 to regulate the

compressed air. Divers sent down to inspect the work reported that the piles were driven to grade without brooming and were accurately spaced. Only occasionally was it necessary to do any sawing off under water. One of the chief advantages of this method of submarine driving is that, even in deep water, long piles are not needed to extend above the surface; the length of piles with this rig need be only a foot or so more than the actual depth of penetration.

Advantages of Method—Summing up the advantages of the method, these points are made: Shorter piles, with saving of lumber; elimination of a follower; full force of blow delivered direct to pile head; piles driven straight; piles accurately spaced by means of spud; no need of unwatering cofferdams for driving; no delays on account of high water; divers not required except for inspection and occasional sawing off.

The work described is being done for the Brooklyn Edison Co. by the Frederick Snare Corp., New York City.

Conclusions From Core-Drill Tests of Concrete Roads

New Jersey Records Furnish Unexpected Information on Influence of Reinforcement and Nature of Cracks

BY R. B. GAGE

Chemical Engineer, State Highway Commission, Trenton, N. J.

CORE drills make it possible easily to determine the strength, character and thickness of any concrete pavement or foundation. The samples taken represent the concrete better and supply more data than cylinders or cubes cast during construction. The location of reinforcing metal, the character of expansion or construction joints and the nature of cracks can easily be determined. This equipment has also made it much easier to detect errors in construction and determine the causes than was possible before its use. The general conditions, governing the construction of pavements, as interpreted from the cores cut to date, may be classed as follows:

1. The thickness of a concrete pavement or foundation will not vary from the thickness specified more than $\frac{1}{2}$ in., if the contractor performs his work in the manner required. When the thickness of the pavement departs more than this amount from that specified, it is very good evidence of careless workmanship.

2. There does not appear to be any definite relation between the strength secured on samples prepared during construction and the strength test shown by the cores cut from the same pavement after construction. The variation is so marked that it has been deemed advisable to discontinue taking sample cubes or cylinders during construction and depend altogether upon the cores taken after construction to determine the character and thickness of the concrete.

3. The position occupied by reinforcing fabric or bars is definitely shown. Reinforcing metal that was supposed to be installed from 2 to 3 in. from the base of the pavement has frequently been found resting on the subgrade.

4. The character of the concrete beneath a reinforcing fabric frequently differs from that on top of the fabric in that it does not have the same density.

5. The porosity of the concrete appears to increase as the slump decreases. The quantity of porous con-

crete appears to be much greater in pavements containing reinforcing metal than in those not so reinforced for the reinforcing metal has a tendency to bridge over the concrete and form openings.

6. The quantity of porous concrete increases with the size of the aggregate, other conditions being the same.

7. Stone aggregate is more prone to bridge and form openings around reinforcing metal than gravel.

8. Cores cut on transverse expansion joints have shown that the bitumen in a premoulded joint filler often is completely squeezed out, leaving only the felt or paper edges; also that there is practically no adhesion whatever between the concrete walls of the joint and the surface of the joint filler.

9. Another important fact, demonstrated to date by the core drill is that cracks are more prone to form in concrete having a low crushing strength than in concrete that has a high crushing strength. The general character of the cores also indicates that the higher the crushing strength, the better the concrete is able to resist the ravages of travel and climatic changes.

10. In order that the different errors in construction may be reduced to a minimum by correcting them as soon as possible after they are made, it is recommended that all concrete foundations and surface pavements be sampled during construction as soon as the concrete has attained sufficient strength to permit the cores to be cut and the crushing strength of these cores determined when they are 28 days old. Such a method of sampling will be much more satisfactory than to wait until the construction of a pavement or foundations has been completed or partly completed. If this procedure is followed, a contractor will soon know, after his job is completed, whether his work is to be accepted at par or at a reduction in price.

11. It has generally been assumed that most of the transverse cracks in concrete pavements start from the bottom of the slab and work to the surface. Some of the cores cut indicate that just the reverse is true. Cores cut on well defined surface transverse cracks, which extend completely across the pavement, showed that the cracks did not extend the full depth of the pavement. In some instances, these cracks have extended through two different lines of reinforcement; other cracks have extended through only single lines of reinforcement. The reinforcing metal appears to prevent longitudinal cracks from opening up; but it is very difficult to tell as yet from the cores cut whether a reinforcing metal decreases the number of cracks in the pavement or not. They do appear, however, to indicate that more benefit would be secured by placing the reinforcing metal adjacent to pavement surface than to base.

New Hudson River Power Plant

The Moreau Manufacturing Co. has just announced that it is about to undertake a new power development on the Hudson River just above the Sherman Island development, now nearing completion for the International Paper Co., above Glens Falls. This new development, which is to be partly used by the International Paper Co., is called the Cedar Dam Hydro-Electric Development. It will utilize 17 ft. of head with preliminary output of 7,500 hp. and a final one of 12,000 hp. The work is in charge of A. H. White, engineer, for the International Paper Co., and is to be done by the Parklap Construction Co., which is also completing the Sherman Island development.

Analysis of Attendance at Engineering Schools, 1921-22 and 1922-23

Abstract of a paper presented before the annual convention of the Society for the Promotion of Engineering Education, Ithaca, N. Y., June 20-23, by Walton St. John, specialist in rural and technical education, United States Bureau of Education, Department of the Interior, Washington, D. C.

THE Bureau of Education has collected educational statistics of engineering schools for several decades. These statistics have been published in recent years as a part of the biennial survey of education and consequently are from one to two years old before they reach the public. Engineering statistics of State-controlled universities and colleges have been published annually but these data necessarily are a year old or more before publication.

In order to overcome the delay in obtaining these statistics the Bureau of Education with the co-operation of the Society for the Promotion of Engineering Education has obtained the enrollments in engineering schools for the year 1921-22, and 1922-23. The enrollments have been obtained for the first semester of each year, and tabular summaries of these enrollments have appeared in the journal of the Society.

With these figures it has been possible to ascertain the enrollments of the graduating classes in the several branches of engineering and also to predict with some degree of assurance the enrollments of the graduating classes for the year following.

There are 133 engineering schools which report to the Bureau of Education, but the data of this study are based upon the reports of only 129 of these institutions.

The table given below shows that losses are recorded in the five leading branches of engineering, the per cent of

In a comparison that has been made between the enrollments in the junior and the senior classes for the year 1922-23, it was found that there was an average loss of 16 per cent in the senior classes. For 1922-23 the junior classes average 9 per cent less than for 1921-22. Therefore the total senior enrollments for 1923-24 will be about 9 per cent less than for 1921-22 and will approximate 9,100, the senior classes having enrolled 9,955 for 1922-23.

The relation of the number of students in schools of engineering to the enrollments in the secondary schools and also to the total number of students in universities, colleges and special training institutions (including in this group all schools requiring for admission graduation from a secondary school) is as follows for the year 1919-1920:

	Per cent
Percentage of engineering students, 51,908, in relation to total male enrollment in secondary schools, 1919-1920, 1,114,833	4.7
Percentage of engineering students, 1922-1923, 52,290, in relation to total male enrollment in secondary schools, 1919-1920, 1,114,833	4.8
Percentage of engineering students, 51,908, in relation to total male enrollment in universities and colleges, 1919-1920, 324,977	16.0
Percentage of engineering graduates, 9,157, in relation to male secondary school graduates, 1919-1920, 101,106	9.0

Partial Pavements for New Subdivisions

STREET improvement practice in subdivisions has been modified in some instances recently, in St. Louis, Mo., by substituting what is virtually rural concrete-road construction for standard city pavement extending the full width between curbs. The accompanying sketch indicates the construction and its future incorporation into a full-width pavement. The advan-

All other branches.....	1922	3,938	1,322	991	6,251
	1923	4,570	1,499	1,437	7,506
		+632 +16%	+177 +13%	+446 +45%	+1,255 +20%

loss varying as follows: mining engineering and metallurgy, 8 per cent; mechanical engineering, 11 per cent; civil engineering, 12 per cent; electrical engineering, 5 per cent; chemical engineering, 24 per cent. The other branches of engineering taken together record a gain of 20 per cent.

tage of the plan is, first, economy—a paved roadway is secured without an excessive cost burden on the bordering unimproved building lots. Second, spaces are left on each side for installing underground conduits and house services without tearing up pavement. The third advantage is that the original pavement is fully capitalized as a major part of the base for a full-width pavement. As the subdivision builds up and standard city paving is warranted, the old concrete is widened on each side, curbs are built and a bituminous surface is spread over the old and new concrete between curbs.

In the original construction, of course, the concrete slab is built to grade as established by the Board of Public Service of St. Louis and from plans by and under inspection of the engineers of the Board. While the partial-pavement type of subdivision street improvement is not required—companies developing subdivisions sometimes preferring to pave and curb the full street width—it is advised, and, in a number of instances, has been adopted, it is believed, to considerable advantage to those buying and building in the new settlement. W. W. Horner, engineer, Board of Public Service, has been largely instrumental in creating the new practice.

Highway Progress and Problems in the Mid-South—III

South Carolina	North Carolina

Seven Southern States Contemplate Road Expenditures Approaching a Billion Dollars—Automobile License Fees and Gasoline Taxes Will Provide the Money—Editorial Review Based on Studies in the Field

This is the third article of the series. The first article, on Group Problems and the two Carolinas, appeared in "Engineering News-Record" of July

26, 1923, p. 128 and the second article, on the two Virginias, appeared in the issue of Aug. 2, p. 168.

Kentucky and Tennessee

IN THE similarity of their highway problems, Tennessee and Kentucky are more nearly twin states than are the two Virginias or even the two Carolinas. Both have about the same traffic, physical, and financial conditions. In Kentucky centralized state direction is most advanced but the effects of recent county domination are still felt. In Tennessee county co-operation in state road development remains a dominant factor. The population is about equally sparse and traffic is overwhelmingly local; not over 2 per cent of the vehicles recorded in traffic counts are foreign to the county in which the counts were made, considering the average for the state.

Finance and administration are the outstanding highway problems. Both states lack development of inter-county and across-state routes. Their present funds scattered about among the counties promise no immediate system development of continuous routes. There have to be larger expenditures and they have to be controlled by the state highway department to build up a connected system of roads if either state is soon to take rank among states which lead in highway development.

Kentucky

Recovering from Local Control

Despite legislation in 1920 which established strong centralized state direction of road improvement, Kentucky has a legacy, from past county direction, of debt and unrelated improvements which presents a difficult problem. Without a large increase in road funds its solution will, indeed, be long delayed. Comprehensive highway financing is the pressing need of the Blue Grass State.

In its general aspects the situation in Kentucky is typical of a situation rather general in southern states. Years of county control of roads have left the state with a system composed of unimproved roads and of improved roads having no relation to each other and also with a mess of responsibilities for up-keep and refunding which it is not financially equipped to manage. Change of administration from county to state has not endured long enough to have formulated and harmonized their necessary interrelations and there is a clash of state, regional and county interests which hinders adequate state highway financing. There is a lesson in noting how these conditions have arisen.

Kentucky in 1912 established a State Department of Public Roads with a commissioner as its chief officer. From 1912 to 1914, however, the duties assigned the commissioner were purely advisory to county officials,

no funds having been appropriated for state participation in road building and no means being granted to compel adoption of the recommendations made to the county.

In 1914 a forward step was taken. The General Assembly declared the inter-county-seat system of some 8,000 or 10,000 miles to be proposed state highways and created a state road fund out of the license tax received from motor vehicles and a 5c. ad valorem tax on all property. This fund was distributed to the counties each year for road construction under the supervision of the commissioner, in proportion to their assessed valuation, no county receiving more than 2 per cent of the fund. Counties were, however, permitted to anticipate their annual apportionment from the state road by voting bond issues and expending the proceeds under the provisions of the act, reimbursement for the state's share of the cost to be received in future years in annual installments equal to their apportionment of the road fund. The fiscal court of the county was permitted to designate each year any of the inter-county-seat roads for improvement under state aid, and the surveys and plans of the proposed work were made, subject to the approval of both the court and the commissioner.

From 1914 to 1916 the maximum amount that the state road fund received each year did not exceed \$750,000 and as the counties put up an equal amount this was all the money available for the construction and reconstruction of 8,000 to 10,000 miles unless a county elected to vote bonds for expenditure under the act, which was done by many counties. Under this law the counties were required to maintain all roads built with state aid. But as there was no penalty for their failing to do so, and as they had but small revenue for such purposes, but little attention by the fiscal courts was paid to this provision. The state aid law continued in force and effect until July 1, 1920, with the exception of minor revisions made by the General Assemblies of 1916 and 1918 relating to the making of surveys and plans by the engineers of the road department instead of those employed by the fiscal courts, and changes in the apportionment whereby the state participated in accordance with the assessed valuation of a county and not on a basis of 50 per cent to each county. Authority was also given to the commissioner to co-operate with the United States in the handling of federal-aid appropriations to the state, pledging the road fund to that purpose with priority over distribution to the counties under state aid.

Though several hundred miles of mediocre roads, disconnected one from the other, were built in the period

between 1914 to 1920, it became apparent that, if the state system of highways connecting all county-seat towns was ever to be constructed, the mileage embraced in the inter-county-seat system must be materially reduced and its construction and maintenance be placed under the direction of the state highway department, with the responsibility fixed. During this time it has been conclusively shown that as long as the initiative in state road construction and maintenance was left in the hands of the average fiscal court, with the right to perform such work with the county forces regardless of plans and specifications, just so long would state

department be obligated to pay each year out of its revenues.

2. A large maintenance charge: In the proposed primary system of state highways 862 miles were constructed under the provisions of the former state aid law, and the state highway commission is required to maintain such parts of this 862 miles as meet the requirements of a state highway or that have been brought up to those requirements by the counties.

Handicapped by the old state-aid obligations and by the requirement of the law of 1920 that construction must be simultaneous from 54 construction centers, these conditions exist:

1. The state is building and maintaining patches of road here and there without any considerable length of continuous road anywhere.

2. It is impossible with the available funds to construct within a reasonable time a connected system of inter-county and trans-state roads.

It is proposed to meet the financial requirements by a bond issue of \$50,000,000 at the rate of \$10,000,000 a year. Legislation providing for a referendum vote on this bond issue failed at the last session of the legislature apparently because (1) the size of the debt was frightening to the people who were accustomed to thinking in county units; (2) the fear was general that increased taxes would be imposed; (3) there was regional and county jealousy. In brief the people had not been educated to think of highways in the modern terms of quantity production and correlated state systems. This task of educating the public prior to the next legislative assembly is the work primarily before those who are promoting road improvement in Kentucky.

Tennessee

Learning Finance and Administration

Tennessee like Kentucky lacks money for highway system development. Roads are being built, many of them are of high type, but they are disconnected. The state has no continuous inter-county routes of significance, nor is it working effectively toward them or toward trans-state lines. Continuity of direction and policies in highway affairs has been interrupted by a changed state administration. Determined official thought is not evident and popular thought is uninformed. Definite policies of finance and development are indicated only in the bond promotion plans of the Tennessee Good Roads Association.

County co-operation is the theory of state road development in Tennessee. An act of 1913 amended in 1919 enabled counties to raise bonds for highway purposes. The counties have been prompt to take advantage of this privilege. In 1922 the 70 counties of Tennessee had voted bonds for road building to the amount of \$34,365,000. Of the total voted, \$27,780,500 have been issued and the par value of the bonds sold is \$27,345,000. The amount authorized but not issued totals \$6,585,000. Of the bonds issued \$4,487,000 were for federal and state-aid projects, while the counties themselves issued \$22,933,500 for the construction of local roads. Primarily to meet federal-aid a one-mill property tax was assessed in 1919, all funds in excess of the amount of federal-aid to go to the counties for expenditure on state roads. In 1919 was passed the bill establishing a state highway department and creating a road fund by establishing license fees on automobiles,

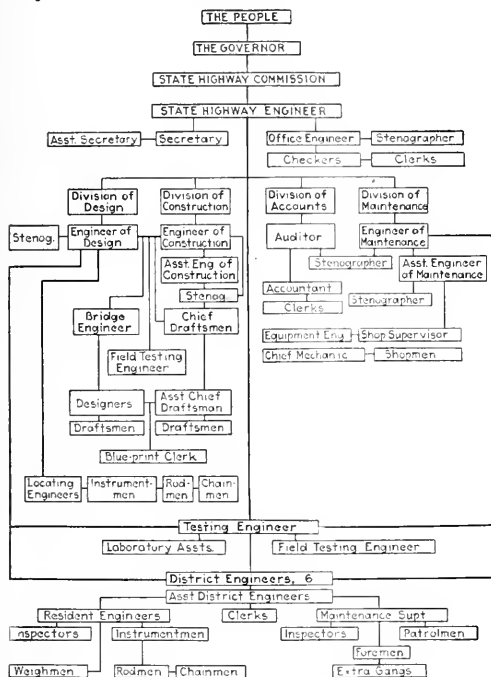

FIG. 6—KENTUCKY HIGHWAY COMMISSION ORGANIZATION CHART

funds be unwisely expended and a poor type of construction obtained.

The General Assembly of 1920, realizing the facts, abolished the state aid law, save for the completion of such contracts as were under way prior to July 1, and enacted in its place the present law, under which the Department of State Roads and Highways, as it is now known, is operating. They declared approximately four thousand miles of the inter-county-seat system to be proposed primary state highways and limited the expenditure of state and federal-aid funds to this system. The administration of the department was placed under the direction of a bi-partisan state highway commission which has developed the organization shown by the chart Fig. 6.

The legacy left the new organization by the preceding eight years of county direction was:

1. A large refunding debt: The operation of the state aid law, by which counties were permitted to vote bond issues, created a debt that will amount to \$500,000 per annum for the next four or five years, which debt the

FIG. 3—TEST CURVES—4-IN. ROTARY FLOW PUMP

face of the impeller. As this ratio is a constant the device operates equally well at all lifts.

Provision is made whereby a small amount of fluid is allowed to pass through the balance disc by means of a small aperture to a recess next the suction stuffing box, thus furnishing high-pressure fluid as a seal at that point. Anyone who runs low-lift pumps will readily concede that this is a desirable result.

The blades are detachable, but are fastened in a manner which makes them easily removable for any purpose. This allows a large variation of pitch and speeds, making it possible to standardize one casing for a large range of capacities, heads, and speeds. The method of fastening consists essentially in first cutting a series of parallel circumferential grooves on the blade ring (or in its absence the hub). On each blade there are cast as many lugs as there are grooves on the blade ring. These lugs are set in advance of each other in such manner that lugs of adjacent blades superpose each

FIG. 4—MODEL PUMP USED IN MAKING TESTS

other. The fastening bolts, set parallel to the shaft, each fasten in double shear one lug each of as many blades as there are grooves. Ordinarily there will be only as many bolts as there are blades, and all blades are independently removable with ease. As diffusion (directing) vanes are not necessary they are omitted, thus making for better general efficiency and reducing the liability of choking to a minimum. Smoothness of operation and balance are thus assured, as all blades are cast from the same pattern.

A study of Figs. 1, 2a, 2b, 2c, will readily bring out the above. Fig. 3 is a chart showing the results of tests run on the 4-in. test pump shown in Fig. 4. The tests conducted according to standard rules for testing show, when size, lift, and capacity are considered, a broad variation of speeds, a steadily increasing delivery for increasing speed and constant lift; a high specific speed; a large increase of delivery at the very low lifts, with well sustained delivery over the whole range of lifts. On the very low lifts, up to the point of design, the efficiency is very high for a pump of its size under the operating conditions, and the efficiency is well sustained at all other lifts, giving a high average efficiency. The brake horsepower curves show a very constant power demand over the whole range of lifts, and as in order to get maximum plant efficiency it is desirable to have the prime mover always operate as near as possible to its best rating this is a very desirable feature. The efficiencies shown compare more than favorably with the efficiencies of the best types of other pumps of equal size operating at equal capacities and against equal heads, for which it has been possible for the author to secure records.

Tennessee Power Developments

Application for a preliminary power permit covering three large projects on the Clinch and Powell Rivers, part of the upper Tennessee River system, has been filed with the Federal Power Commission by the Tennessee Electric Power Co. Applications covering almost the identical sites covered by this application have already been filed by the Knoxville Power & Light Co., a subsidiary of the Electric Bond & Share Co., and by the Tennessee Hydro-Electric Co. One of the three proposed developments is on the Clinch River below its junction with the Powell. The plan calls for the erection of a plant with a 175-ft. head and a dam which will create a storage reservoir 72 miles long. A 40-ft. draft on this reservoir will make 1,000,000 acre-ft. of storage available for stream control purposes, an amount which will equalize the flow of the river and make it possible to develop 100,000 continuous horsepower at this site. The second development is at the upper end of the pool of the first development near the Cheat River station, with a head of 160 ft. and an output of 50,000 hp. The third development is to be on the Powell River near the town of Combs. It will have a head of 180 ft. and an output of 27,000 hp., making a total of 177,000 hp. for the three sites. The Tennessee Electric Power Co. has a present installation of 108,000 hp. in hydro-electric plants at Hales Bar on the Tennessee, another on the Ocoee, and another at Great Falls on Taney Fork. In addition it has three steam plants with a capacity of 59,000 hp. The company reports that its load is growing at such a rate that it will require 40,000 more horsepower within the next four years.

Hints That Cut Cost and Time

For the Contractor and the Engineer

Rule for Computing Angle-Bar Weights

BY PAUL C. TRIMMER
St. Paul, Minn.

IT IS OFTEN necessary to determine the weight per lineal foot of an angle bar when only the thickness and flange dimensions are known, and also the thickness of any given angle knowing only the weight per lineal foot and flange dimensions. Men to whom the billing, stocking and handling of steel from stock are intrusted are, many times, unacquainted with the steel handbook. It is to them that the following method may be of good use.

If one cubic foot of steel is assumed to weigh 489.6 lb., then a square foot (12 in. x 12 in.) 1 in. thick weighs 40.8 lb., and a strip 12 in. long, 1 in. wide and 1 in. thick weighs 40.8 $\frac{1}{12}$ or 3.4 lb. A strip 12 in. long, 1 in. wide and $\frac{1}{32}$ in. thick is equal to $\frac{3.4}{32}$ lb. or 0.10625 lb. or 0.1 lb., say. It can be seen from the foregoing that a strip of metal 12 in. long and 1 in. wide has $\frac{1}{32}$ of an inch in thickness for every $\frac{1}{32}$ of a pound in weight.

Example: 12 in. of a certain 3x3 angle weighs 7.2 lb. per lineal foot. The sum of the flanges is 6 in. If 6 in. = 7.2 lb., and 1 in. of this particular thickness weighs $\frac{7.2}{6}$ or 1.2 lb., or $\frac{12}{10}$ lb.; and if $\frac{1}{10}$ lb. is $\frac{1}{32}$ in. thick, $\frac{12}{10}$ lb. is equal to $\frac{12}{10} \times \frac{1}{32}$ or $\frac{3}{10}$ in., which is the thickness required.

Rules:
$$\frac{\text{Weight per foot} \times 10}{\text{Sum of Flanges}} = \text{the number of thirty-seconds in thickness; also the number of thirty-seconds}$$
$$\times \text{sum of flanges} = \frac{\text{weight per foot}}{10}$$

These simple rules may be easily be memorized by anyone and computed mentally.

Successful Means of Removing Hard Spots From Filter Beds

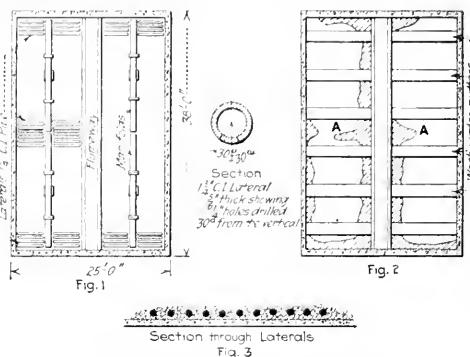

BY W. COMPTON WILLS
Assistant Engineer of Distribution, Water Department,
Wilmington, Delaware

UNDER-DRAINAGE difficulties in the operation of mechanical filters often give the water-works engineer considerable difficulty. The means by which these difficulties may be overcome are well demonstrated in the experience of the writer at the Wilmington plant. Soon after the plant was put in operation in 1917, "hard spots" appeared in the filter sand. The size of the spots increased until about one-third of the filtering area was affected. Various methods of removing the spots were tried, such as increasing the vertical rise of the wash water, ejecting water pressure by perforated pipe, and ejecting water pressure through hose into the hard areas. In some instances, even, the hard portions of the filtering area were dug out. All such means proved only temporary, so the conclusion was

reached that the faulty wash was caused by some undiscovered condition existing in the under-drain or strainer system of the beds.

In the latter part of 1920 permission was granted to tear out and thoroughly examine the sand, gravel, and strainer system of a filter bed. After such an examination methods were devised to overcome the faulty wash. Early in 1921 this filter bed was turned back into service and up to the present time it has been free from hard spots and has remained level over its entire filtering surface.

The strainer system of these beds as shown by Fig. 1, consists of four 6-in. x 9-in. cast-iron manifolds, two placed end to end and running longitudinally and spaced

UNDER-DRAINAGE SYSTEM OF FILTER PLANT

one-half way between the side of the filter and the flumeway shown in the center of the bed. Leaded into these manifolds are 1 1/2-in. east-iron laterals on 6-in. centers and drilled every 6 in. of length with two holes, 1 in. in diameter, facing downward at an angle of 30 deg. from the vertical. The center line of each lateral is 3 in. from the filter floor.

The hard spots appeared in the locations and approximate shapes shown by Fig. 2. The trouble seemed to be around the walls and a particularly bad place appeared over the ends of the manifolds (Section A-A, Fig. 2).

Upon removing the sand and gravel muddy deposits were found that had not been removed by the wash water. Upon inspecting the laterals, it was discovered that in several instances the large gravel (for which specifications called for a layer 9 in. thick of such size as would pass a 2 1/2-in. circular opening and be retained on a sieve with 1-in. circular openings) had become wedged against the laterals and cemented over the 1-in. holes, and thus had stopped the flow of the wash water to this portion of the bed. The next step was to remove all the laterals and manifolds. In the ends of some of these laterals were found debris and laitance, so located as to stop from the inside the proper distribution of the wash water. The material had probably gotten into the system during construction, when because of war-

time conditions proper selection and supervision of labor was difficult.

The conclusion at this point was drawn from our findings that the small $\frac{1}{4}$ -in. holes of the laterals were not free enough to deliver, and the voids of the coarse gravel not open enough to allow a sufficient quantity of wash water to be collected above the entire strainer system before it was forced on its vertical rise. In correcting this condition the laterals were dipped in a preparation which would not give taste to the water and were replaced into the manifold. About these laterals and manifolds were placed blue granite stone screen tailings. The tailings selected were mostly laminated stone varying in size from 2 in. x 4 in. x $\frac{3}{4}$ in. to 5 in. x 6 in. x 2 in., and having all shapes. Spaces beneath the laterals were left entirely open, the laminated stones forming side walls along the laterals. Enough tailings were placed over the laterals to cover the pipes and any large voids between the heavy stones. Next, the old courses of gravel were replaced, followed by the filtering sand.

This filter has been in continuous operation since the first part of 1921 and the sand remains perfectly level at the present time. This bed has a sand area of 735 sq.ft. The washing is done by high velocity wash-water, without air or mechanical agitation. A vertical rise of wash-water equal to 27 in. is being used on this filter bed and the difficulties previously experienced in washing have entirely disappeared.

Craftsman Type Architecture for Industrial Buildings

ENGINEERS who are concerned with the development of architectural details in industrial buildings will be interested in the new plant which is being built for the Latham Litho & Printing Co. at Long Island City. For a manufacturing plant this building presents a novel appearance. It is not the idea of the Latham company to disguise the fact that they are using the plant for manufacturing, but rather to express the individuality of their business. They believe that this craftsman type of architecture accomplishes their purposes, and although the two facades shown in the sketch give the building an impractical appearance for a manufacturing plant the cross-section in the accompany-

be of steel sash of the cottage casement type. The saw-toothed roof will be covered with a standard tar and gravel roofing. As the face of the building is along the elevated tracks of the Long Island R.R., the gable will be provided with three spaces for standard bill posters where the Latham company will display copies of the posters which they print in their plant.

Walter Kidde & Co., Inc., are the architects and engineers, as well as the builders of this plant, and have engaged McDonnell & Peare of New York to design the facades.

Setting Forms on Vertical Curves for Concrete Paving

BY RAY E. BEHRENS

County Highway Engineer, Waukesha County, Waukesha, Wis.

REGARDLESS of the nicety of the finish on a concrete road it will not possess desirable riding qualities unless the form setting is good. Little trouble

METHOD OF FORM SETTING ON VERTICAL CURVES

is experienced in getting a satisfactory job on tangents and on straight grades. But vertical and horizontal curves frequently present difficulties to the form setter, as is evidenced by many completed jobs in which practically all curves, horizontal as well as vertical, consist of a series of angle points joined by chords. This is especially true of vertical curves, where poor form setting is not so noticeable to the eye, but where it is, however, decidedly deficient in riding qualities.

ing sketch shows that its saw-toothed roof provides a very practical floor layout.

The building will have a floor space of about 60,000 sq. ft. which includes lounging and lunch rooms for the employees and a garage for trucks and employees' automobiles. It will be set back about 70 ft. from the building line and this area, together with the rest of the land surrounding the property, will be laid out in an attractive park. The first story will be built of tapestry brick, the upper story of half timber and stucco, and the roof will be green shingle tile. The windows will

On tangents and on straight grades stakes should be set with a transit every hundred feet to line and to grade. Intermediate stakes can be set with sufficient accuracy by means of Swedish T-stakes. Where vertical curves are circular and not parabolic, the following method has been found extremely practical and simple of application. When correctly applied perfect vertical curves will result.

On vertical curves stakes should be set to grade every 50 ft. with an instrument. The form setter then determines by means of his T-stakes and an ordinary rule,

how much the 50-ft. stake is above or below the two adjacent 100-ft. stakes (regular stations), depending upon whether the curve is a "crest" or a "sag."

Fig. 1 represents a "crest." Here the form setter will "T" between Sta. 8 and 9 showing that the grade stake at Sta. 8 + 50 is 5 in. above a straight line from Sta. 8 to Sta. 9. Call this distance "A." He will then stretch a chalk line tightly to grade between Sta. 8 + 00, 8 + 50 and 9 + 00. At the 25-ft. points, i.e., at Sta. 8 + 25 and 8 + 75 he will set auxiliary grade stakes, the grade points of which will be $\frac{1}{2}$ of "A" or $1\frac{1}{2}$ in. above the chalk line. Raising the chalk line to the grade points at the 25-ft. stakes will reveal the outline of the vertical curve. However, his final step will be to raise his forms by $\frac{1}{2}$ of $1\frac{1}{2}$ in. or $\frac{3}{4}$ in. above the chalk line at each 12 $\frac{1}{2}$ -ft. point. If the engineer or the inspector on the job will furnish the form setter with the value of the distance "A" it will save him the operation of "T"ing between the station stakes. "A" can readily be computed from the plan elevations.

Fig. 2 represents a "sag" or a "trough." Here, again, stakes are set to grade by instrument at Sta. 16 + 00, 16 + 50 and 17 + 00. The form setter by the use of his T-stakes has determined that Sta. 16 + 50 is 4 in. ("A") below a straight line from Sta. 16 + 00 to Sta. 17 + 00. After stretching his chalk line tightly from Sta. 16 + 00 to 16 + 50 and from 16 + 50 to 17 + 00, he allows it to drop or sag by an amount equal to $\frac{1}{2}$ "A" or 1 in. at the 25-ft. point. The chalk line will then show a perfect vertical curve, and the forms can be set directly to the line.

The above method of measuring mid-ordinates can be used equally well on horizontal curves.

When once thoroughly explained and demonstrated to a form setter, the latter will pride himself with possessing a "system" and better form setting will result.

Ford Engine Used to Operate Headgates

By WILLIAM ARTHUR

U. S. Indian Service, St. Xavier, Mont.

AT THE Big Horn Headgate, at St. Xavier, Mont., there are five gates, each weighing two tons. When they were geared to a hand wheel to raise and lower

From Job and Office

Hints that Cut Cost and Time

them, it required 64 turns of the wheel to move a gate one inch. This was a slow process; in fact the 64 to 1 ratio proved too slow in cases of emergency. The average water pressure is 11 ft., low water 17 ft. and high water 16 ft.

A Ford engine has been used to move the gates, as shown in the accompanying illustrations. The engine was geared to the hand wheel, with eight control levers, one of which slides the fork clutch into the perpendicular hand wheel, another controls the brake for clutch or speed, a third is the reverse to lower the gates, a fourth is high and low to raise the gates, and the others are for car brake to hold the car in position while in operation, carburetor control, spark control, and transmission lever to move the car to the next gate or to the shed.

The engine runs on tracks with a 6 ft. 1 $\frac{1}{2}$ -in. gage, and about 60 ft. of track suffice for the operation of the five gates.

"Hump Switch Yard" for Power House Construction Job

CONSTRUCTION of power house No. 3 on the Big Creek project of the Southern California Edison Co. involved the excavation of a large amount of loose material from power house and penstock site. This material, added to a natural gravel bar at a bend in the river, made a practically level area several acres in extent, immediately adjoining the power house site. By dumping the material so as to leave the surface with an easy grade inclining upward toward a steam donkey engine in one corner of the area it was possible to lay out a material storage yard in which distribution of loaded cars was made without the use of a switching locomotive.

The accompanying illustration shows the arrangement of the material yard into which cars come from the main line railroad down a long steep incline onto the track in the foreground. Here they are left for

FORD ENGINE, MOUNTED AND RUNNING ON TRACK, GEARED TO HAND WHEEL CONTROLS GATES
At left, forked clutch in mesh to hand wheel to raise and lower gates. At right, headgate built 27 years ago out of native rock

From Job and Office

For Contractor and Engineer

distribution with the aid of only the steam donkey engine at A.

A cable from this engine first draws the car above any desired switch after which the switch is thrown, the car is released and, by means of its brakes, is stopped at the desired point. Reinforcing steel, lumber of various classifications, wood stove pipe, and other materials were delivered in this way.

GRAVITY SWITCH SYSTEM IN MATERIAL YARD

The same steam engine delivered crushed rock from the bunkers in the left foreground to the concrete mixers at the power house which is to the right beyond the limits of the picture. To accomplish this two pulls were necessary; the dump cars were first pulled up the incline from the bunkers, allowed to drop then by gravity to a position behind the warehouse at the right of the picture whence by means of a snatch block and return line the cars were hoisted up an incline to bunkers over the mixer.

Highway Bridge Built of Railroad Car Sills and Ties

BY CROSBY TAPPAN
Tyrone, Pa.

ON THE State Highway between Tyrone and Bellwood, Pa., there was an old covered truss bridge of about 120-ft. span. Last year a colored tourist in a Ford ran into one side of the bridge and knocked it down. As this is a heavily traveled highway the county commissioners of Blair County, who are responsible for the bridge and its maintenance, at once erected a temporary bridge, pending the construction of a new

TEMPORARY BRIDGE MADE FROM RAILROAD MATERIAL

permanent structure. They obtained from the Pennsylvania R.R. twelve old steel car sills and some ties. They built two cribs with the ties, bolting them together and further bracing them with an 8-in. I-beam at each corner. These I-beams were long enough to extend about 3½ ft. above the floor of the bridge; and they carried two lines of steel cable as a guard fence. The cribs were filled with rock.

The bridge, as rebuilt, consists of three spans, 37.5 ft. c. to c., with a clear span of 32 ft. The floor is two layers of 3-in. plank, the upper layer being creosoted. The width of the floor is 12 ft. 8 in. between guard rails. To carry the floor and traffic four old car sills were used, spaced 4 ft. 6 in. c. to c. These car sills are 20 in. deep at the center and 12 in. deep at the ends and are braced together with tie-rods.

This bridge demonstrates engineering ability in meeting an emergency and in making use of available local material so as to keep traffic moving.

Determining Regulated-Flow Duration Curves Graphically

BY DR. GEORGE E. LYON

Rensselaer Polytechnic Institute, Troy, N. Y.

THE WRITER believes that the following graphical method for the determination of the regulated-flow duration curve will be of interest.

In the first place the construction of the natural-flow curve will be reviewed. Table I gives the mean monthly flow of a certain stream in second-feet for a period of four years—sufficient to illustrate the problem. The

lowest value in the table (75 sec.-ft.) is plotted at 100 per cent time (Fig. 1), the second lowest value (also 75 sec.-ft.) is plotted at 97.9 per cent (= 47'48 expressed as a per cent), the third lowest opposite 46 48 (in per cent) etc., there being 48 months during the period under consideration. Any point on the curve will show the per cent of time during which the flow

From Job and Office

Hints that Cut Cost and Time

FIG. 1—DURATION CURVES FOR STREAM FLOW

has been "equal to or greater than" the value of the ordinate at that point.

For the construction of the regulated-flow line, the mass diagram must first be plotted; accumulative discharge in cubic feet vs. time in months. The ordinates for the diagram are given in the last column of Table I, each value representing the total number of cubic feet which has passed the point on the stream under consideration from the time the table was started up to and including the month opposite which this ordinate is plotted. The mass diagram is shown plotted in Fig. 2.

Suppose now that we are to construct the regulated-flow duration curve due to a storage reservoir of 3,000,000,000 cu.ft. capacity. Choose the first "summit" A on the diagram as the starting point and lay off the ordinate AB equal to the capacity of the reservoir to scale. Draw the line BC tangent to the next "valley" (at C) on the diagram, producing it to D, at which point the ordinate DE = AB. The slope of the line BD indicates the rate at which water may be discharged, starting with a full reservoir at B, just emptying it at C and having it full again at D. Repeat this construction at A'B'C'D'E', A''B''C''D''E'', etc. To complete the regulated flow lines by joining D and B', D' and B'', etc., any combination of lines may be used, remembering that the greatest ordinate between the natural- and regulated-flow lines must not exceed the capacity of the reservoir. It will be seen that the ordinate between these two lines at any time is equal to the volume of water in the reservoir at that time.

To get the data from the regulated-flow lines in Fig. 2 for plotting the regulated-flow duration curve (Fig. 1) the time for each different rate may be measured in

TABLE II			
Regulated Flow	Time		
Sec.-Ft.	In.	Per Cent	
		Time	
340	4 30	100 0	
348	5 13	79 2	
372	3 30	60 6	
431	5 25	46 1	
490	0 50	24 3	
544	0 62	22 2	
580	0 50	19 6	
685	2 00	17 5	
781	0 70	9 2	
910	1 00	6 2	
1,270	0 50	2 1	
Σ = 24 00			

inches and the rate of discharge by the slope of the line. In the case at hand the horizontal scale used was 1 in. = 2 months; hence the total length of time (four years) may be expressed as 24 in. From this, Table II may be computed. The first column gives the regulated flow in second-feet, arranged in order of magnitude, and the second column the time in inches during which that rate occurred. Column three is found in the same manner as were the per cent times used in plotting the natural-flow duration curve. The first value (100 per cent) shows that for 100 per cent time the regulated flow would be "equal to or greater than" 340 sec.-ft. The

second value (79.2 per cent) equals $\frac{24 - 4.3}{24}$, expressed in per cent, since the flow would be equal to or greater than 348 sec.-ft. except for 4.30 in. of time, etc. Having completed Table II, the regulated-flow duration curve may be drawn as shown in Fig. 1.

In connection with water-power investigations, if the

FIG. 2—MASS DIAGRAM FOR STREAM FLOW

head is constant, ordinates in Fig. 1 are proportional to power and areas are proportional to energy. Suppose for instance that a capacity of X hp. is considered. Without regulation the water station can develop Y hp. at its driest period. Due to regulation, Z hp. more can be added at low water. If the X hp. is to be continuous, the maximum capacity of an auxiliary station should be W hp. The area a represents the kilowatt-hours output of the water station without storage, area b the output added by regulation and area c the output supplied by the auxiliary station. These areas may be measured in kilowatt-hours per year, in which case the values would be the average yearly outputs over the same length of time as used for the construction of the duration curves. From the figure it will be seen that the auxiliary plant is operated on an average of 41 per cent time or 150 days per year.

Dredging Started for Vancouver Dry Docks

Extensive dredging operations required to provide sufficient depth for the operation of the new floating dry docks at North Vancouver are now well under way; the dredging and filling will take about four months and cost \$400,000.

For Contractor and Engineer

Device for Counting and Weighing Traffic on Roads

WEIGHTS and number of vehicles passing over a highway are automatically recorded by a new device employed in the traffic studies now being made on the Washington-Baltimore road by the Bureau of Public Roads and the University of Maryland. As indicated by Fig. 1, the apparatus consists of a rubber hose, filled

FIG. 1—AUTOMATIC TRAFFIC RECORDER

with water, which is placed beneath the pavement in such a way that the weight of a vehicle passing over it is transmitted to it. A small tube runs from the hose to a standard pressure recording device. A passing vehicle compresses the water in the hose and the pressure is transmitted through the tube to the recording device. There the pressure actuates a lever which makes a record, Fig. 2, on a cylindrical roll of paper and also actuates an attachment for moving the paper to receive a fresh record.

Two sets of apparatus will ordinarily be used, one for the traffic in each direction, and possibly a slight ob-

FIG. 2—TRAFFIC RECORD WITH TEST VEHICLE

struction may be placed in the center of the road to confine the traffic to proper lanes.

The instrument may be calibrated by driving vehicles of known weight over the place where the hose is installed and noting the height of line made on the record paper.

A record covering any desired period of time will show the weight of both front and rear wheels of all vehicles which have passed over the road. Should it be desired the apparatus can be further improved so as to show the time at which the vehicle passes.

Powder Magazine Made From Old Steel Tunnel Forms

IN BUILDING powder houses on the Big Creek project, the Southern California Edison Co. in two instances made use of steel tunnel forms brought to this work after they had served their purpose on another part of the system. These forms consist of steel plates, 2 ft. square, arranged to be set up in parallel rows supported on a steel frame and with internal means of holding inside and outside walls 2 ft. apart.

The powder house shown in the accompanying illustration is 20x60 ft. in plan, inside, and has walls 10 ft. high. The roof is supported on three rows of posts, one row inside each of the side walls and one down the center of the building. The walls were filled with earth

POWDER HOUSE MADE OF OLD STEEL TUNNEL FORMS

and a layer of earth was also placed in the roof, i.e., supported on planks and filling the space between purlins and rafters. The roofing proper consists of corrugated iron.

Powder houses built in this way have been found to be more satisfactory than those built under ground, which are very damp in wet weather.

Cutting Concrete Piles with Dynamite

IN BUILDING a reinforced-concrete wharf at the Pearl Harbor Naval Station, Hawaii, penetration of concrete piling was such that in many cases the refusal point was reached as much as 7 ft. above the desired grade. Lieut.-Commander S. Gordon, Civil Engineer Corps, U. S. Navy, devised a system of dynamiting the piles, says a recent issue of *Explosives Engineer*, which was an adaptation of means previously used on wooden piles.

After exploding a stick of 60 per cent dynamite in a 1-in. horizontal hole cored at the butt of a test pile, the shattered concrete was cut away, the surface smoothed with carborundum, tests for cleavage made on the concrete with magnifying glass and hammer, and the reinforcing bars subjected to bending tests. As both concrete and rods were found undamaged, holes were then cored around the butts of the remaining piles, which were shot in batteries of eight. In no case did the disruptive damage extend farther than 18 in. from the center of the charge.

Letters to the Editor

This department aims to be a forum for the discussion of the views of engineers and contractors. The range of interest should be as wide as possible. Contributors are, therefore, asked to make their letters short.

Another Co-operative School

Sir—Under date of June 14, 1923, p. 1050, you published an article on "Developments in Co-operative Engineering Courses," by Dean R. L. Sackett of Pennsylvania State College.

In the article, he describes the plans in effect at the University of Cincinnati, Massachusetts Institute of Technology, Harvard University, New York University, and Antioch College. No mention is made of the School of Engineering, Northeastern University, although the co-operative plan was established here in 1909 and we will have during the coming year approximately one thousand students in the School of Engineering. The school is a recognized school of college grade offering curriculums in civil, mechanical, electrical, and chemical engineering, and awarding the bachelor's degree.

Boston, Mass.,
July 24, 1923.

CARL S. ELL,
Dean, School of Engineering,
Northeastern University.

Unification of St. Louis Terminals

Sir—In mentioning my talk on the St. Louis freight terminal situation in your report of the American Society of Civil Engineers' convention at Chicago you state that I advocated "improvement and ultimate unit operation" of the freight terminal facilities. This gives a wrong impression, in that it appears to imply my advocacy of operation of all these facilities by a single agency. I believe thoroughly in the consolidation of the classification and transfer of cars interchanged between railroads, but such consolidation need not be performed by a single agency. In fact, there is no reason why it should not be performed by several agencies. I believe that the complete unit operation of railroad terminals in large cities served by many railroads is unsound, and I do not want to be known as advocating unit operation.

It is true that the St. Louis committee on terminal improvements, of which I am a member, recommends a systematic arrangement of outer yards for car transfer movements. But my Chicago talk called particular attention to the fact that the proposal for leaving the St. Louis railroads alone in the individual operation of their local freight terminals was the backbone of our entire report and distinguished it from the reports on the Chicago situation by the Chicago Railway Terminal Commission and the Board of Economics and Engineering of the Association of Security Holders, in both of which reports complete unit operation was recommended. This is explained in the following quotation from the paper which I presented in abstract at the Chicago meeting:

"It is interesting to note that the Board of Economics and Engineering, appointed by the National Association of Security Owners, after a study of the Chicago situation, recommended practically the same kind of a group yard plan of classification and interchange of carload freight. The Board went farther, however, and recommended the complete unification under single control of the entire Chicago terminal. The St. Louis committee does not believe this to be practicable. The latter terminal might be unified if all the railroads possessed equal advantages in location and facilities, but unfortunately that is far from the case."

The words "unification" and "unit operation" have been surrounded by a sort of halo or glamor by those who have advocated the principle, and large sections of the public have come to believe that such operation offers the only

remedy of terminal delays. That is not the case, and a great deal of false effort will be wasted along such lines until there is a clear conception of the difference between the consolidation of certain features of railroad terminal operation, such as, the classification and transfer of interchange freight, which is most desirable, and the unit operation or unification of terminals, which may not be at all desirable, at least in some instances. C. E. SMITH.

St. Louis, Mo., July 27, 1923. Consulting Engineer.

[The paper by Mr. Smith pointed out that "unification of freight handling at St. Louis is in sight." Evidently there is need for a recognized definition of or distinction between the terms unification and unit operation, which at present are used indiscriminately by different writers.—EDITOR.]

Activated-Sludge Tank Under Test at Argo, Sanitary District of Chicago

Sir—In your issue of June 28, p. 1136, Prof. Harold A. Thomas outlines a variation of the activated-sludge tank, which resembles very much a type of tank which has been experimented with by the Sanitary District of Chicago and the Corn Products Refining Co. at Argo during the past year. I attach herewith a cross-section of the tank which

CROSS-SECTION OF ACTIVATED-SLUDGE TANK AT CORN PRODUCTS TESTING STATION, ARGON, ILL.

was suggested in 1920 by Dr. Mohlman to produce circulation, using the general features outlined by Professor Thomas. This tank was installed in the summer of 1921. During the past twelve months this tank has constantly produced a good effluent with 75 per cent of the amount of air used by the ridge-and-furrow system similar to the Milwaukee plant, operated in parallel. However, the eccentric type of plate placing, similar to that used at Manchester, England, and proposed for Indianapolis and the North Side sewage-works of the Sanitary District of Chicago, has been producing a good effluent with even less air. While this peculiarly baffled tank is an interesting one from a standpoint of study, its construction on a large scale would be somewhat expensive and very much more so than the type proposed at Indianapolis and in Chicago.

Our experiments at the present time are directed along the line of finding what the minimum amount of air is that can be used where the agitation is supplied by mechanical means, and further whether activated sludge can be made by mechanical devices alone, without blowing air. We have not yet obtained results sufficient to justify any statements, but believe that the line of investigation will be helpful in defining future lines of research.

LANGDON PEARSE,
Sanitary Engineer, the Sanitary District of Chicago.
Chicago, July 17.

News of the Week

CURRENT EVENTS IN THE CIVIL ENGINEERING AND CONTRACTING FIELDS

News Brevities

Expenditure of Over \$11,000,000 on the New York, Chicago & St. Louis R.R. and allied lines, including the Hocking Valley and the Lake Erie & Western, is announced by the president of the N. Y., C. & St. L. \$6,000,000 will be spent on improvements to the system and \$5,000,000 on equipment.

Further Improvement of Alligator and the Four-Mile Creeks to facilitate large traffic in the coastal area near Georgetown, N. C., is asked by a delegation which appeared before the Board of Engineers for River and Harbor Work of the Corps of Engineers. The Board has recommended that a survey of this area be made to determine the cost of such work.

An Early Test of the Constitutionality of the Act of 1921, which requires the licensing of civil engineers and surveyors in Pennsylvania, is forecast by George D. Stevenson of Scranton. Mr. Stevenson stated that the action would be based on the decision against the Act by Judge Samuel Shull of the Monroe County Court. Governor Pinchot vetoed the bill repealing the act.

The Five-Span Wooden Bridge crossing the Delaware River between Stockton, N. J., and Centre Bridge, Pa., was destroyed by fire July 22. The bridge was a covered one and was erected 82 years ago. It was the only structure of its kind between Trenton and Easton, Pa., a distance of more than 50 miles, to withstand the great freshet of 1893. It is probable that the bridge will not be rebuilt.

A Supercable Between New York and Rome, with capacity of 50,000,000 words a year on a line 4,500 miles long by way of the Azores, will be built jointly by the Western Union Telegraph Co. and the Italian Submarine Cables Co. under a contract signed last week by the two companies. This will be the longest and highest capacity cable across the Atlantic and the direct line to Rome will save hours of time over indirect transmission via England and France.

River Gravel for Track Ballast is to be used extensively by the St. Louis Southwestern Ry., the state legislature of Arkansas having ratified an agreement giving the railway company a 10-year right for the removal of sand and gravel from the bed of the Ouachita River near Camden, Ark. It is stated that this is first class material and can be applied at less cost than any other ballast obtainable, while the supply is unlimited. A ballasting program has been outlined extending over a period of years, with a view of completely reballasting the main line already ballasted or ballasting where no ballast has yet been applied.

Road Bond Bill Causes Missouri Highway Department Concern

Attorney General Jesse W. Barrett, of Missouri, has been requested to construe the appropriation act passed by the last legislature providing for the issuance of \$5,000,000 state road bonds in 1923, \$10,000,000 in 1924, and \$10,000,000 in 1925.

The legislature so worded the act to read that \$10,000,000 be issued in bonds in 1924 and 1925. Worded in this manner the act might be construed to mean that only \$10,000,000 could be issued during both years, while members of the State Highway Commission intended that \$10,000,000 be issued each year.

To Build Two New Subways in New York City

The Board of Estimate and Apportionment of New York City, at its meeting on Aug. 3, approved the routes of the proposed Washington Heights and Brooklyn Crosstown subways. The Washington Heights subway will be from 162nd St. on St. Nicholas Ave. to 124th St., to Manhattan Ave., to 110th St., to Central Park West, and south to 59th St. where it will be connected with one of the existing subways. The Brooklyn Crosstown subway will extend from Newtown Creek in Greenpoint generally along Manhattan Ave., Roebling St., and Bedford Ave. to Halsey St., Brooklyn. The connections for this subway have not yet been decided upon. The estimated cost of the two subways is \$54,250,000.

General Goethals to Report on Intracoastal Canals

In view of the favorable action upon the report of Col. G. M. Hoffman, district engineer at New Orleans, regarding the proposed inland waterway from the Mississippi River at New Orleans to Corpus Christi, Tex., the Intercoastal Canal Association of Louisiana and Texas has retained the services of Gen. George W. Goethals to investigate the commercial possibilities of this canal. General Goethals will make an exhaustive study of the commercial aspects of such a canal, not only as a local transportation facility in Texas but with special reference to its relation to the inland waterways of the Mississippi valley. The Intercoastal Canal Association is desirous to have this canal so constructed that it will accommodate the same class of traffic as is now using the Mississippi and Ohio Rivers. For this purpose the canal should have a depth of 9 ft. and a bottom width of 100 ft. Such a canal would mean that barges on these two rivers could be operated along the coast of Texas and Louisiana and eventually to the Mexican border.

The Corps of Engineers has ordered that a survey be made to determine the cost of such a canal between New Orleans and Corpus Christi.

Harding's Death To Affect Coal Situation

To Undertake Mediation In Present Situation Means Employment of Sympathetic Understanding

Washington Correspondence

The President cannot die without affecting all industries and most individuals. The death of Mr. Harding comes at the worst possible time in so far as it affects the coal situation. It is certain to have a very direct bearing on the questions of labor relations which are now in such an acute stage.

While those who are in a position best to appraise the situation are convinced that there will be no strike, they must admit that the situation is one in which a crisis might develop at any time. Government intervention is more likely now than ever before in peace time, due to the fact that the public is not inclined, after the experiences of the last few years, to be kept in suspense as to its fuel supply.

DIPLOMACY REQUIRED

Enough has been learned in the last few years of Government intervention to make it very clear that it is a diplomatic rather than an executive undertaking. To undertake to mediate in such a situation as exists today in the anthracite region means the employment of diplomacy such as is implied by the better sense of the word,—the use of sympathy and understanding. Such a task can be undertaken only by a person in whom each side has confidence. Whatever may be said about Mr. Harding's greatness as an executive, no single individual in the land will dispute that he was a man of friendship—a man with an intense desire to do the right thing. He commanded the respect of capital and labor alike because they knew he was big-hearted and would do his best to be fair. On the other hand, the public would have been satisfied with his mediation. People generally do not have an opportunity to go into the details of issues. They would have been willing to abide by his conclusions. The man so amply suited to undertake mediation has been removed suddenly. It is true that the country is to be spared the airless drifting which marked the administration's policy just before and during the strike of 1919. At that time there was great uncertainty as to the extent of President Wilson's incapacity. No one was sure whether or not the pronouncements coming from the White House were those of the President or of someone else. Later it was established that some of these pronouncements, at least, did not come from the President himself.

In the present situation, the uncertainty is of a different character. There naturally will be delay before the new helmsman will feel confident to take the ship of state into the main channel. The situation is complicated by lack

of knowledge as to what the new President may do. The outstanding achievement of his career is his handling of a labor matter. His action at Boston in connection with the strike of policemen brought him into national prominence and secured for him the praise and support of those who believe a firm stand must be made against the exactions of labor unions. That act, however, antagonized labor. It is certain the United Mine Workers would hesitate a long time before they would agree to accept President Coolidge as final arbiter of questions which to them seem vital. Unquestionably labor unions are not at all sure, but that one of the principal opponents of their policies has been elevated to the presidency. They must recognize that since Mr. Coolidge first came to national notice because of his stand against unionism, it would be only natural were he to be of the opinion that the public approves of such a policy. His experience in Boston may have convinced him that unionism must be curbed and that nothing can be gained by temporizing with it. In such a case he might conclude that the anthracite situation offers a splendid opportunity to put his views into effect.

On the other hand, many think Mr. Coolidge will take this opportunity to demonstrate that he is not opposed to labor unions when properly conducted. He may admit the right of the United Mine Workers to demand all that they have and to strike if they do not get what they ask. At best, however, it is admitted on all sides that the prospect of agreement is less auspicious today than it was yesterday.

A CRITICAL TIME

Many doubt that the check-off is the real objective of the United Mine Workers. The rank and file of that organization is so much more interested in wage than in any of the collateral issues, that it is not probable that the necessary support will be forthcoming to insist upon the check-off. The check-off means a great deal to those who are responsible for the financing of the international union but it means much less to the member of a local. The heads of labor unions are like political leaders or the heads of European states in that they can go only so far in persuading their people to accept solutions which are distasteful to them.

Signs are multiplying that the anthracite workers are ready to insist on the increase. Apparently the more conservative leaders, like the heads of the international union, will have great difficulty in avoiding a suspension unless they can promise a wage increase. During the last strike it was claimed at first that the anthracite workers were being held out to win for the bituminous workers, and that if they were left to themselves they would return to work. Exactly the reverse proved to be the case. It was nearly a month after the Cleveland agreement before work was resumed, and even then the terms of settlement were all but rejected when the ratification convention met in Wilkes-Barre. Steam roller tactics had to be employed to get ratification through and even then it carried by a small margin. New factors have entered since then to bolster up the determination of anthracite workers. They elected Capellini. They not only

Woman Succeeds as Highway Contractor in California

When her husband died three years ago and left a \$175,000 road building contract to be finished Mrs. Ellen E.

O'Brien of Martinez, Calif., decided that the business reputation which her husband had built up should not be impaired. So she undertook the completion of the contract. The job on which Mrs. O'Brien entered the field of highway contracting was the

Franklin Canyon Highway, a 9-mile concrete road which she finished in August, 1921. Since that time she has undertaken numerous other contracts and completed them successfully, putting into her work genuine enthusiasm and love for the job. Contracts which she has completed in the past three years include the Marsh Creek highway, a short railroad for the Henry Cowell Lime & Cement Co., a 3-mile concrete road in Napa County, and the 4-mile Moraga Boulevard in Contra Costa County. This latter job was a \$95,000 contract, and Mrs. O'Brien finished it thirty days ahead of schedule despite unusual difficulties met in prosecuting the work.

Mrs. O'Brien is an enthusiastic supporter of the Associated General Contractors of America, having attended its latest annual convention held in Los Angeles.

North Carolina Lets Contracts for 136 Miles of Road

The North Carolina State Highway Commission on June 27 let contracts on 21 highway projects totaling 136.23 miles. The total cost of the work, exclusive of the usual ten per cent for engineering and contingencies, is \$2,567,254.

Of this 43.31 miles are of standard concrete or asphaltic paving, 16 and 18 ft. wide. The average cost per mile, including grading, draining, structures, paving, and all other construction items, is \$34,953. There are 3.07 miles of penetration macadam, which costs, with the same construction items as above, \$23,334 per mile. The remainder of the work consists of 89.85 miles of earth, top-soil, and one-course gravel roads, which cost \$10,632 per mile, including clearing, draining, grading, surfacing, structures and all other construction items. The structures (reinforced-concrete bridges and culverts) included in the above figures cost \$481,868, an average of \$3,537 for each mile of road to be built.

elected him but they did it by a large majority. For a time after his election, Capellini seemed to have joined hands with the conservative leaders but now that he has been accepted as a member of the negotiating committee, he has come out with a statement that he will not surrender any demand and that he will press each one of them. With the death of the President and with unmistakable signs of increased determination on the part of the mine workers, the prevalent opinion in Washington is that the situation has taken on new seriousness.

Iowa Board of Engineering Examiners Organized

The Iowa State Board of Engineering Examiners has been organized with the following membership: Seth Dean, chairman, Glenwood; L. M. Martin, vice-chairman, Atlantic; Alvin LeVan, Des Moines; B. F. Fleming, Iowa City; and C. S. Nickals, Ames. All correspondence or business matters for the board should be addressed to W. C. Merckins, secretary, State House, Des Moines, Iowa.

Province Has No Jurisdiction Over Railway Bridge

In a decision rendered by the Supreme Court of New Brunswick on the suit by the provincial government to compel the Canadian Pacific Railway to raise the height of its bridge over Reversible Falls, St. John, it has been held that the province has no jurisdiction over the bridge. This decision was rendered after hearings occupying more than a year, in which alleged obstruction to shipping and the danger to the bridge in raising it to a higher elevation were points of contention.

City Planning Division, Am. Soc. C. E., Elects

At the organization meeting of the City Planning Technical Division of the American Society of Civil Engineers, at Chicago, on July 12, a temporary executive committee was chosen as follows: Chairman, N. P. Lewis, New York City; secretary-treasurer, Charles B. Ball, Chicago; together with Harland Bartholomew, of St. Louis, Mo., and E. A. Fisher, Rochester, N. Y. It was decided that it would not be practicable to provide the city planning program for the Richmond meeting of the society in October.

Opposition to Amendment of Transportation Act

Arguments against early amendment of the Transportation Act, as now proposed tentatively and particularly as to providing for compulsory consolidation of the railways, are being issued by the Railway Business Association. It is pointed out that permissive consolidations, as provided for by the Act, have not yet been tried and that the Interstate Commerce Commission is at work on an official plan to which mergers must conform. A sudden change to a compulsory requirement would undo much of the progress already made, it is believed. Furthermore, such a step would produce complicated litigation, or as the Association's letter says, "would guarantee not consolidations but lawsuits."

Conditions prevailing since the passage of the Act in 1920 have prevented any test of rate making, but under present rates a record-breaking business has been handled, railway credit is rising and a great program of improvement work has been undertaken. The Association urges further trial of the present Act without amendment, and suggests that the whole matter should be the subject of competent inquiry by a joint congressional committee to report to the next session of Congress.

Oregon Engineers Urge Congress Probe Ousting of Davis

Protesting against the recent dismissal of A. P. Davis, former director of the Reclamation Service and his replacement by C. W. Davis, not an engineer, the Oregon Technical Council, which is composed of delegates from local sections of the American Society of Civil Engineers, American Society of Mechanical Engineers, American Institute of Electrical Engineers, American Institute of Architects, National Electric Light Association, and the American Institute of Mining and Metallurgical Engineers, has sent a letter to its congressmen urging that Congress investigate reasons for Mr. Davis' dismissal. The Oregon Technical Council also calls attention to the fact that it believes "the civil service law was evaded since the abolishment of the office of director and the substitution thereof of that of commissioner, with identical duties and responsibilities, is a mere subterfuge which should not make it possible to do indirectly what the law forbids to be done directly."

"This is one of the cases," continues the Oregon engineer's letter, "where the enforcement of the civil service law would have been most beneficial to government service, and it is a phase which we believe deserves the closest scrutiny."

The Oregon engineers stand behind Mr. Davis both for his "ability and efficiency as a business man and as an engineer." The Oregon engineer's letter further states that allegations made that Mr. Davis is not a business man and that his office involved a duplication of work "appear to us so manifestly unfounded as to amount to mere excuses. The excellent showing made by the Reclamation Service, the loyalty and faithfulness of its employees, and the confidence of the people and the Congress in the Service, demonstrate clearly both the business and the engineering ability of the former director."

J. C. Stevens is president of the Oregon Technical Council and F. H. Murphy is secretary.

Street Widening Proposed in Philadelphia

A project for the widening of Ninth St. in downtown Philadelphia from Vine St. to South St., has been approved by the Board of Surveyors, and submitted to City Council in the form of an ordinance. The proposed widening is by taking 15 feet off each side of the street, increasing its width from 50 to 80 feet. The assessed valuation of the property required is \$3,100,000. It is proposed that the widening shall be extended over a period of years so that the cost for condemnation shall be kept a minimum. The ordinance now before Council places the 80 feet width on the city plan, and all future building will be on the new line.

The Board of Surveyors some time ago approved plans for the widening of Vine St., 7th St., Pine St. and 20th St., to form a traffic circuit around the central business section. The proposed widening of Ninth St. is not a substitute for that plan, but an addition to it, affording an intermediate wide street. The ordinance for widening the other streets to form the traffic circuit has been in the hands of City Council for about six months.

To Measure the Water Diverted from Niagara River

The Canadian Government has agreed to the plan proposed by the United States for the measurement of the diversion from the Niagara River. The measurements are to be made under the supervision of a board to be composed of two members, one to be appointed by the Canadian Government and the other by the United States. The American member of the board undoubtedly will be Major P. S. Reinike, the District engineer of the War Department at Buffalo. Canada is expected to appoint William Stewart as its member of the board.

Steel Erection Begun on Delaware River Bridge—Philadelphia

The first shipment of steelwork for the main towers of the Delaware River Bridge, consisting of pedestal sections for the north leg of the tower on the Philadelphia side of the river, was received at the site of the work on July 9.

ANCHORAGE CABLE BENT FOR THE DELAWARE RIVER BRIDGE

Sketch showing how it will look at the end of the first stage. The anchorages will later be completed with an outside structure of granite. Anchorage of the cables is effected by a series of eyebar chains, shown diagrammatically in the drawing.

Erection was commenced at once, and is progressing rapidly. Each pedestal consists of eight fabricated sections, and is 5 feet 6 inches in height and 38 feet 8 inches by 26 feet 1 inch in outside dimensions. Fabrication of other portions of the tower steelwork is progressing rapidly in the shops and shipments will be made soon. The two towers are being constructed by the Bethlehem Steel Co., at its shops at Steelton, Pa.

Contract Let for Second Narrows Bridge at Vancouver

Contract was signed on July 26 for the construction of a railroad and highway bridge across the Second Narrows of Burrard Inlet at Vancouver, B. C. This structure, which has been under consideration for more than a decade, will connect the city with North Vancouver by a crossing whose total length will be about 3,000 ft. This will be made up of 685 ft. of steel spans, about 500 ft. of creosoted pile approach and the remainder of earth fill. The steel trusses will include one 300-ft. span, a 185-ft. single leaf bascule and a 150-ft. approach span. Shorter spans will also be required for crossing Lynn Creek. The structure will be at low level, clearing high tide by about 12 ft. There is a 90-ft. depth of water where the central piers will be sunk. The design will be for a single track railroad with Cooper's E-50 loading and a vehicular roadway cantilevered on either side.

Contract for the work is held by the Northern Construction Co. working in conjunction with J. W. Stewart. The total cost will be slightly over one million dollars, for most of which bonds will be taken by the contractors. The costs are being divided as follows: North Shore municipalities, \$630,000; Vancouver, \$200,000; Dominion of Canada, \$100,000; Province of British Columbia, \$100,000. Construction is to be started in the month of August, and it is estimated that two summer seasons will be required to complete the work.

Agree on Joint Board to Inspect Transit Facilities

In connection with the proposed inspection of the structures and equipment of the New York subways and elevated lines for which engineers of the Westinghouse Electric and Manufacturing Company and the General Electric Company and Dr. George F. Swain have already been engaged, the State Transit Commission and the City Transit Bureau have come to an agreement whereby a joint board will be constituted to proceed with this survey. The Transit Commission will be represented by Robert Ridgway and George Gibbs, the Board of Estimate by Dr. George F. Swain, and the Interborough Rapid Transit Co., by George H. Pegram, and the Brooklyn-Manhattan Transit Co. by Eugene Klapp and W. G. Gove.

"Drive slow—see our town;
Drive fast—see our jail."

Test Section of Automatic Train-Control Works Successfully

An automatic train-control system has been put in operation on the 50-mile branch of the Pennsylvania R.R. between Lewistown and Sunbury, Pa., and the twelve locomotives which constitute the equipment of this line have been equipped with the necessary apparatus, so that all passengers and freight trains are now subject to this control. For this system a track circuit operates cab signals and an air-brake connection on the locomotive. In the cab are three electric lamps. When lamp A is alight the engine man knows he has a clear track for at least two block sections, but if he should try to exceed the maximum speed allowed on the division the air brakes will be applied automatically. When lamp B is alight it indicates one clear section and the mechanism holds down the velocity of the train to an assigned "medium speed" limit.

The third lamp is a "slow" or "stop" signal as conditions may require, and its indication is given about 1,800 ft. before the train reaches a section occupied by another train or having an open switch. If this light burns and the engineman takes no action, the train control devices will apply the brakes and stop the train. But if the engineman acknowledges the signal by throwing a lever, he can proceed at an assigned "slow speed" with his train under perfect control. Any attempt to exceed this speed will result in application of the brakes. The Lewistown branch is chiefly single track, with automatic visual signals at intervals. On half the length of the line these signals operate in connection with the train-control system, but on the other half the dispatcher controls them.

C. & O. Ry. Betterments \$14,800,000

The improvement program of the Chesapeake & Ohio Ry. for 1923 includes little in the way of extension but is based on the more intensive development of its existing lines with a view to handling maximum tonnage at minimum cost, as stated by W. J. Harahan, president of the company. The estimated cost of work authorized and under way, but exclusive of new equipment, aggregates \$14,815,000, of which \$12,777,000 is for road and the remainder for equipment improvement.

Freight yards and passing tracks will total \$8,322,517, including \$3,630,000 for a new yard at Clifton Forge, Va.; \$380,000 for storage yard at Newport News; \$285,750 for yard additions at Hinton and Silver Grove, and \$4,025,767 for various yard work and for building and extending passing tracks and other side tracks. Next to this big item comes \$1,586,266 for shops and engine terminals, shop machinery and coal and water stations. Grade reduction at Paynes, near Covington, Va., will cost \$468,000 to reduce grades of 0.4 per cent eastbound and 1.13 per cent westbound to level track. Additional main tracks will cost \$446,900, including ten miles of third track between Big Sandy Junction and Russell, Ky. Other items include \$116,633 for track realignment at Hinton and Beckley, \$500,752 for bridges, trestles and culverts, \$424,738 for stations and office buildings, \$368,764 for signals and interlocking plants.

Second Incinerator for St. Louis

Bids for the second of a proposed series of five garbage incinerators, with a capacity of consuming 100 tons of garbage in 24 hours, will be received by the Department of Public Utilities, St. Louis, Mo., on Aug. 28. The first incinerator has been in operation for about seven months with successful results and without any complaint from the public.

New Orleans Planning and Zoning Commission Appointed

A city planning and zoning commission of twenty members has been appointed by the Commission Council of New Orleans, under an ordinance adopted May 1 of this year. Of the twenty members, seven are appointed at large and thirteen represent various organizations. J. Frank Colemann, consulting engineer of the New Orleans Dock Board, and one of the members at large is a member of the executive committee of the Commission. Among the organization representatives on the Commission are: the Louisiana Engineering Society, J. W. Billingsley; Louisiana Chapter, American Institute of Architects, Allison Owen; New Orleans Contractors & Dealers Exchange, Richard McCarthy.

The planning commission is given wide authority to study all phases of city planning, including the laying-out of undeveloped real estate. It is also authorized to prepare plans for zoning the city into residential, commercial and industrial purposes. The powers of the planning commission extend to all territory three miles beyond the city limits. No recommendation of the commission has legal effect until accepted by an ordinance of the Commission Council.

Besides money appropriated for the use of the planning commission by the City Council the planning commission is authorized to receive contributions of money or materials to be expended at its discretion but subject to the audit of the Commission Council.

Passaic Valley Outfall Sewer Tunnel Contract Rescinded

Formal notice that it vacated its contract for the construction of the outfall sewer tunnel into New York Harbor was presented July 26 to the Passaic Valley Sewerage Commission by the contractor, the Holbrook, Cabot & Rollins Corporation of New York City. The action is based on refusal of claims made by the contractor for extra cost resulting from alleged misrepresentation by the commission at the time the bids were secured as to the character of the ground through which the tunnel passes. A total of \$794,668 of damages is claimed by the contractor. Any payment is refused by the commission which also denies that it misrepresented the conditions in any way. Pending permanent arrangements the commission, by agreement with the contractors, is continuing construction with the contractor's plant and workmen. Twice previously this tunnel has been the object of trouble between the commission and its contractors. The original contract was let to John F. O'Rourke who abandoned the work and filed suit for damages as related in *Engineering News-Record* June 3, 1917, p. 268, and July 25, 1918, p. 191. The second contractor was Charles A. Haskins of Boston who abandoned his contract.

Engineering Societies

Calendar

Annual Meetings

NEW ENGLAND WATER WORKS ASSOCIATION, Boston, Mass.; Annual Convention, Burlington, Vt., Sept. 18-21, 1923.
INTERNATIONAL ASSOCIATION OF STREET SANITATION OFFICIALS, Chicago, Ill.; Annual Conference, Chicago, Sept. 27-28, 1923.
AMERICAN PUBLIC HEALTH ASSOCIATION, New York; Annual Meeting, Boston, Oct. 8-11.
AMERICAN SOCIETY OF CIVIL ENGINEERS, New York; Fall Meeting, Richmond, Va., Oct. 17-20.
AMERICAN SOCIETY FOR MUNICIPAL IMPROVEMENTS, St. Petersburg, Fla.; Annual Convention, Atlanta, Ga.; Nov. 12 to 16.

The Colorado Engineers Council gave a banquet in honor of R. H. Keays, chief engineer of the Moffat Tunnel Commission, on July 31 at Denver, Colo. W. F. R. Mills of the Denver Union Water Co. presided, and L. G. Carpenter, president of the Colorado Engineers, spoke on "The Engineer and His Position to the Community."

Personal Notes

CHARLES T. BRAGG has opened offices in the General Motors Bldg., Detroit, under the firm name of Bragg Engineering Co., for consulting service in chemical, civil, mechanical and electrical engineering. Mr. Bragg's professional record includes being president of the Detroit Board of Water Commissioners, director of the American Institute of Metals, technical director for Berry Brothers, chemical engineer for the Ohio Brass Co. and works manager for the Michigan Smelting & Refining Co. Associated with the company as consulting engineer is COL. T. A. LEISEN, who was the engineer in charge of construction of Camp Custer, past president of the American Water Works Association and former general manager of the Detroit Department of Water Supplies. Recently Col. Leisen has been designer and engineer in charge of construction of the new Detroit filtration plant, which was described in *Engineering News-Record*, May 17, p. 860.

FRED J. MILLER, Center Bridge, Pa., has been appointed engineer member of the Water and Power Resources Board of Pennsylvania, a new board created by the administration reorganization code in the Pennsylvania Department of Forests and Waters to take the place of the Water Supply Commission of the state.

MAJ. GEORGE H. NORTON, city engineer of Buffalo, N. Y., for the past 14 years, has been appointed chief engineer of the consolidated Terminal and Grade Crossing Commissions of Buffalo. Mr. Norton is a graduate of Cornell University. In his service in

Buffalo he directed the Buffalo River improvement, the Scajaquada Creek storm water drain and harbor improvements. COL. CHARLES E. P. BABCOCK, formerly first assistant engineer of Buffalo, becomes city engineer, succeeding Maj. Norton.

W. C. BROWN, a former city engineer of East San Diego, Calif., has completed a course at Leland Stanford Jr. University and has gone to Sonora, Mexico, on an irrigation project.

PROF. CHARLES DAVID MARX, emeritus professor of civil engineering at Leland Stanford, Jr., University, has received an honorary degree from the Technical University at Karlsruhe, Baden, Germany.

BURGIS G. COY, civil engineer of Fort Collins, Colo., has been appointed resident engineer of the eastern portal of the Moffat Tunnel. Mr. Coy is a graduate of Rensselaer Polytechnic Institute, and after some time spent on tunnel work in New York State he went to Colorado where he was engaged on construction of the Laramie-Poudre tunnel; his paper on this tunnel won the Thomas Fitch Rowland award of the American Society of Civil Engineers.

MAJ. E. L. DALEY of the U. S. Corps of Engineers has been appointed engineer officer in Pittsburgh, Pa., succeeding Maj. J. Franklin Bell who some weeks ago was transferred to Washington as engineer commissioner for District of Columbia. Maj. Daley has for several months been doing Red Cross work in Greece and Russia and prior to his work abroad was an instructor at West Point.

ROBERT LLOYD, borough manager for the Borough of Edgeworth for the past three and one-half years, has accepted the position as manager of the Midland Improvement Co. and the Midland Water Co. at Midland, Pa., both subsidiaries of the Crucible Steel Company of America.

H. B. NOWLIN, civil engineer, has accepted a position with the George T. Wilhelm Co., construction engineers of Cedar Rapids, Iowa. Mr. Nowlin has specialized in engineering management and construction machinery. He is now located with the above firm at Elaine, Ark., where they are just completing a 61-mile concrete road.

HON. J. R. COOKE, M. P. P. for North Hastings, Ontario, has been appointed a member of the Ontario Hydro-Electric Commission, and J. G. Ramsden has been removed from membership of the Commission, which is being reorganized by the Provincial Government.

E. W. OLIVER, general superintendent of the Niagara, St. Catherine's & Toronto Ry., has been appointed manager of that road and of the Toronto Suburban Ry. and the Toronto Eastern Ry., and is now superintending the completion of the last named railway.

F. C. PALMER has been appointed town engineer and street commissioner of Bowmanville, Ontario. Mr. Palmer had been for many years engaged in municipal engineering work at Oshawa, Ontario.

GEORGE W. BORDEN, state highway engineer of Nevada, was elected secretary of the Western Association of State Highway Officials at the session held July 10 and 11 at Salt Lake City, Utah.

WILLIAM J. P. SIMPSON announces the opening of offices at 4417 White Bldg., Seattle, Wash., for the practice of civil and industrial engineering. Mr. Simpson had for the past three years been associated with the Continental Pipe Manufacturing Co.

I. KELLERT, formerly assistant town-engineer of St. Lambert, Province of Quebec, has been appointed town-engineer to replace E. Drinkwater, who has resigned.

W. BOYD JONES has opened offices in the Sunderland Bldg., Omaha, Neb., under the firm name of the American Construction Co. and will do a general construction business.

FREDERICK A. DALE, formerly with George F. Hardy, consulting engineer, New York, has become principal assistant engineer with L. F. Harza, consulting engineer, Chicago, whose principal work at present is on the design of the 270-ft. rock fill dam on the Dix River, Kentucky, for the Kentucky Hydro-Electric Co., a subsidiary of the Middle West Utilities Co.

Obituary

WALTER L. KEISER, traveling representative for the Pittsburgh Meter Co., Pittsburgh, Pa., died at his home in Waco, Tex., May 26, after a brief illness. Mr. Keiser was foreman of the company's water meter shops for a number of years before entering the sales field.

CHARLES D. BLANEY, of Saratoga, Calif., chairman of the original California state highway commission and long active in the good roads movement in the state, died July 25. Mr. Blaney was born in Chicago and graduated from Princeton University. In 1882 he moved from Chicago to California. As member and chairman of the state highway commission, he had a great deal to do with the laying out and construction of the highway system under the first bond issue of \$18,000,000.

CHARLES J. CONNELL, president and founder of one of the oldest contracting firms in Chicago, the Fitzsimons Dredge & Dock Co., died in Evanston, Ill., Aug. 2, at the age of 84. In 1872 he gave up a position as bank cashier and formed a partnership with Mr. Fitzsimons, their first contract being the Dearborn St. bridge, the first in Chicago to be operated by steam. Since that time the firm has constructed 80 per cent of the bridges (or of their substructures) in Chicago, well over fifty in number. The California St. bridge is now under construction and work was started Aug. 5 on the Adams St. bridge. In 1875 the 12-ft. Fullerton Ave. tunnel, one of the largest water tunnels in Chicago, was driven by this company from the lake to the river. Other waterworks structures were the Carter Harrison, Four-mile and Wilson Ave. cribs, and several more tunnels.

From the Manufacturer's Point of View

A Point of Contact
Between Maker and User of
Construction Equipment and Materials

Conference Discusses Standards for Tilting Mixers

At a second concrete mixer conference arranged by the Associated General Contractors of America and held in Chicago July 30 and 31, the main subject was the standardization of tilting mixers. This supplemented the previous meeting on standards for non-tilting mixers, as reported in *Engineering News-Record* of July 5, p. 36 and 19, p. 120. In addition, there was considerable discussion as to changes in the requirements for standardization of mixers in general.

For the tilting mixers one of the main points of discussion was the selection of sizes, which had been proposed tentatively as No. 3, No. 4 (or 5) and No. 7. The outcome was that the meeting did not adopt, but "recommended for adoption," Nos. 3½, 5 and 7. The manufacturer is to state the least angle at which the drum mixes its rated batch efficiently and the capacity of the drum is to be taken as its water level content at this angle. A schedule of the standardization requirements for tilting mixers will be issued shortly, and in many respects will be similar to that for non-tilting mixers, given in *Engineering News-Record* of July 19, p. 120.

In regard to mixers in general, a table was submitted giving the quantities of mixed concrete for the various proportions of mix and giving also the size of batch of various proportions for each standard size of mixer. It was decided that this table should be copyrighted. A schedule of charges for the Association's nameplates on standard mixers was also submitted.

To insure adherence to the adopted standard sizes it was proposed that all non-standard sizes should be eliminated by January, 1925, and that manufacturers continuing to make such non-standard mixers should forfeit the right to use the "standard" name plates for their entire line of mixers. This restriction will not apply to mixers above No. 28 and below No. 3½, which are the limits of the standard sizes.

Newaygo Co. To Build Cement Plant in Wisconsin

A million-barrel (annual) cement plant is to be built in Manitowoc, Wis., by the Newaygo Portland Cement Co. duplicating the recently enlarged capacity of the plant at Newaygo, Mich. Limestone will be shipped across Lake Michigan to Manitowoc from the company's quarries in the Calcite and Petoskey district of Michigan. The new plant is to be located near the site of the Manitowoc Shipbuilding Corp., the steel handling facilities of which will be used to expedite the construction of the cement works.

The Wisconsin plant is to be built and operated by a subsidiary, the Manitowoc Portland Cement Co. With the construction of the new plant new interests from the west side of the Lake enter the company, including the Mani-

towoc Securities Co. and the Manitowoc Ship Building Corp. Wellborn & Huntington, consulting engineers, Chicago, made the investigation and report on the marketing facilities available at Manitowoc as well as the supply of raw materials.

Program Outlined for Caterpillar Service School

For users of caterpillar tractors the Holt Manufacturing Co. announces that a service school at Wausau, Wis., will open Aug. 13 and continue one week under the supervision of H. H. Chambers, director of the company's service division. The object of the school is to acquaint tractor users with proper methods of operation and maintenance of their equipment. A carload of specially cut-away motors, transmissions, and other assemblies will be used to illustrate, disassemble, and reassemble. Cut-away models of carburetors, magnets, air cleaners, and other parts will enable the students to learn about operation and adjustment. The company states that there will be no tuition or registration fee charged for the school.

Census Figures Show Scope of American Industry

The Department of Commerce announces that a summarization of the reports made to the Bureau of the Census by the manufacturing establishments in the United States shows that the value of their products aggregated \$43,653,283,000 in 1921, as compared with \$62,041,795,000 in 1919 a decrease of 30 per cent. Compared with the value of products reported for 1914 there was an increase of 80 per cent due largely to the rise in prices.

A better index of conditions will be found in the figures relating to persons engaged in manufacturing. The average number of wage earners employed in 1921 was 6,946,564, or 23 per cent less than the number reported for 1919, while there is very little difference between the figures shown for 1914 and 1921.

The census statistics for 1921 relate only to establishments having products valued at \$5,000 or more.

SUMMARY OF MANUFACTURING PLANTS FOR THE UNITED STATES: 1921, 1919, AND 1914

	1921 ¹	1919 ²	1914 ³
Number of establishments	196,267	214,383	177,109
Persons engaged	8,252,376	10,688,849	8,117,895
Proprietors and firm members	172,871	250,571	259,172
Salaries and wages	1,377,941	1,838,219	962,533
Wage earners (average number)	6,946,564	9,000,059	6,896,190
Value of products	\$10,763,442,000	\$13,342,655,000	\$5,342,157,000
Value added by manufacture	2,563,118,000	2,880,868,000	1,274,458,000
Cost of materials	8,200,324,000	10,461,787,000	4,067,719,000
Wages	51,580,000	462,994,000	198,720,000
Value of products	25,338,617,000	37,288,731,000	14,358,935,000
Value of products	43,653,283,000	62,041,795,000	23,967,860,000
Value added by manufacture	18,314,666,000	24,753,064,000	9,628,925,000

¹ Statistics for 1921 do not include 54,054 establishments employing 40,865 wage earners (average number) with products valued at \$136,715,000, each reporting products under \$5,000 in value.

² Data for establishments with products under \$5,000 in value have been eliminated from certain of the items shown, as follows: For 1919—number of establishments, 60,215; wage earners (average number), 41,252; value of products, \$151,631,000. For 1914—number of establishments, 95,409; wage earners (average number), 127,495; value of products, \$228,654,000. For the other items in the table, separate data for this number, 127,495, value of products, \$228,654,000. For the other items in the table, separate data for this number, 127,495, value of products, \$228,654,000. For the other items in the table, separate data for this number, 127,495, value of products, \$228,654,000. For the other items in the table, separate data for this number, 127,495, value of products, \$228,654,000.

³ Value of products less cost of materials.

Gives Course in the Best Use of Forest Products

Demonstration courses in the best and most economical use of the products of our forests are offered by the Forest Products Laboratory, Madison, Wis.

Details of the several courses offered for personal instruction are given in Miscellaneous Circular No. 8, just issued by the United States Department of Agriculture. These courses are given in the kiln drying of lumber, boxing and crating, gluing of wood, and wood properties and uses. They are arranged to be completed in from one to two weeks and so that a fee of \$100 to \$150 will be sufficient to cover the cost of the course.

Stress is laid on the practical aspects of the subjects, so that no one need hesitate to enroll because of a lack of technical training. Copies of the circular may be secured from the United States Department of Agriculture, Washington, D. C., as long as the supply lasts.

Road Work Organized in Brazil—Foreign Construction Reported

A number of important public and private works planned or under way in foreign countries have been reported to the Department of Commerce. Road improvement ranks high among these projects.

Plans have been formulated by the Minister of Public Works of the Province of Buenos Aires, which will put highway construction in that province on an organized basis, with funds regularly appropriated for the purpose. Only \$370,000 a year will be available at first, but it is planned to levy a land tax to increase this amount.

The city of Sao Paulo, Brazil, has made a contract with a local firm to asphalt 100,000 sq. meters of its streets.

The province of Quebec, Canada, will spend \$5,000,000 on roads during the coming summer.

The Brazilian government has awarded a contract to a Brazilian company to construct a naval base in Rio Grande Do Sul with a training school. The total cost is estimated at 8,000,000 milreis. The city of Sao Sebastiao do Paraíso, Brazil, plans to contract for a loan of 1,000,000 milreis for civic improvements.

The Greek government has asked for proposals for the partial construction of the port works planned for the improvement of Piraeus, the port of Athens.

Midwest Terra Cotta Firms Fined

Six terra cotta manufacturing concerns, charged with violations of the Sherman anti-trust act, entered pleas of guilty last week before Federal Judge Cliffe, sitting in Chicago, and fines ranging from \$1,500 to \$3,000 each were imposed. The firms are located in Chicago, St. Louis, Kansas City and Denver.

Business Notes

MCWANE CAST IRON PIPE CO., Birmingham, Ala., has opened an office in Dallas, Texas, with J. L. Hill as manager in charge. This office will cover the entire Southwest and Mexico. The firm makes the McWane pre-calked joint and a complete line of cast-iron pipe.

ELK MANUFACTURING CO., of New York City, has been taken over by the Elk Machine Tool Corp., with increased capitalization. The new company will continue to manufacture and sell precision tools under the Elkin patents. The line of tools consists of machine tools for shaving, burnishing and squaring bearings used in internal combustion motors, valve-lifters, air-compressors, Elk terminals and other precision tools. J. G. Elkin, inventor and mechanical engineer, is president of the new company and will have entire charge of the manufacturing and production.

EQUITABLE EQUIPMENT CO., INC., New Orleans, announces the purchase from the Santa Fe R.R. of approximately 16,000 tons of relaying rail varying in size from 50 to 60 lb. per yard.

CONTRACTORS EQUIPMENT CO., INC., Detroit, has just completed a large addition to its warehouse and service station for the handling of road and general construction machinery. The location of the new plant is central to the building activities of Detroit.

THOMAS H. DALLETT CO., Philadelphia, manufacturer of pneumatic stone-working machinery and supplies, has purchased a new factory at 165-189 West Clearfield St., Philadelphia, and moved into its larger and more modern plant July 1.

WHITE CO., Cleveland, announces the recent purchase by the City of New York of 100 2-ton motor trucks on a single order. The trucks are equipped with dumping bodies and are for the use of the Department of Street Cleaning. The grand total of White trucks in the city's service is now 551.

KERR TURBINE CO., Wellsville, N. Y., has just undergone a reorganization through the acquisition of practically all its common stock by new interests. Paul B. Hanks, the former president, having disposed of his holdings, has resigned and has been succeeded by W. T. Hamilton of Pittsburgh.

A. J. SWANSON, district manager at Atlanta, Ga., for the North Western Expanded Metal Co., has been transferred to Los Angeles to take charge of the company's Pacific Coast territory.

Equipment and Materials

German Metal-Spraying Process Exhibited at Leipzig Fair

The growth of metal spraying processes in Germany was evidenced by the interest shown in the exhibits of Meurer'sche A. G., of Berlin, at the recent Leipzig Fair, according to reports received by the U. S. Department of Commerce. The devices are claimed to be improvements upon the M. A. Schoop (Swiss) patents of 1909-1911, which covered the process of fusing various metals by means of a hydrogen gas blow pipe or electric current and spraying the molten particles with compressed air. A special company was formed which conducted extensive researches and finally in 1920 N. Meurer obtained about twenty patents which the exhibiting firm now controls. The process is intended to spray aluminum, lead, bronze, iron, copper, brass, nickel, zinc, tin, gold and silver upon the surface of cement, textiles, glass, porcelain, cast-iron, wood, stonework, cardboard, paper, wrought iron, or any other metal articles, covering them with a layer of 1/40 mm. or thicker if desired.

The apparatus is made in the shape of a hand pistol or a tumbler drum with one or more spraying pistols in action. A wire of the required metal is automatically fed through a nipple at one end and as it approaches the other end it is melted by a current of oxyhydrogen gas under high pressure or oxyacetylene gas and the atomized particles are forced out in a jet through a nozzle. The hand pistol is guided in whatever direction work must be done. The jet does not scorch paper or any other inflammable material. It is claimed that the sprayed surface will readily lend itself to polishing and buffing. The primary object of the process is to weatherproof or otherwise protect surfaces subject to oxidation or corrosion.

Truck-Mounted Crane Kept Busy on Variety of Jobs

How one contractor kept a truck-mounted crane busy on a variety of jobs is illustrated by the case of the Peter Herkner Motor Trucking Co., Cleveland. The equipment consisted of a full-circle swing crane, with separate 40-hp. gasoline engines, manufactured by the Universal Crane Company, Elyria, Ohio, and mounted on a used 5-ton motor truck. The outfit handled a 3-yd. clamshell bucket with teeth.

One of the first contracts on which the crane was used was the removal of a 100-yd. ramp in a large building

excavation which had been left in order to get the steam shovels out. The crane, located at the end of the excavation, dug out the material with the clamshell bucket and loaded it into trucks.

Two cellar excavation jobs each involving 300 cu.yd. of excavation, followed. The mobility of the crane reduced to a minimum the time lost in getting from one job to another. When this work was finished the crane was sent to a gravel pit for loading trucks. While this work was in progress there occurred a garbage strike in Cleveland and the truck-mounted crane was drafted for the emergency work of unloading garbage from cars to pit or trucks.

Instead of laying this crane up for the winter, the owner arranged with

Steam Shovel Clears Snow-Blocked Road

With the aid of a steam shovel the six-mile road from Narada Falls to Paradise Valley in Mt. Rainier National Park, Washington, blocked by snow 7 ft. deep, was opened up to traffic this spring a number of weeks earlier than usual. The equipment, illustrated

above, consisted of a 3-yd. Osgood shovel of the revolving type mounted on crawler traction. Similar use of a steam shovel for handling snow was noted in this journal June 7, p. 1022, for clearing the Snoqualmie Pass through the Cascade Mountains in Washington.

the city to handle coal for schools, thus demonstrating the all-year-round service of this equipment. Various odd jobs also were found in and around industrial plants in handling scrap iron to and from cars, pig iron. With the aid of a special bucket an attempt will be made to use it on snow-removal work.

Illuminated Traffic Control Unit

For the control of motor vehicle traffic at street intersections, the Line Material Co., South Milwaukee, Wis., has developed an illuminated unit known as the "Traficon," consisting of a steel casting in the form of a hood extending 81 in. above the street surface. At each side of the hood facing the intersecting streets a bullseye lens

is set in a recess perpendicular to the pavement. On either side of the lens, as shown in the accompanying illustration, a heavy flange protects the glass from injury and its recessed position in the hood is such as to reduce to a minimum the possibility of damage by vehicle wheels.

To serve its purpose most effectively, the manufacturer states, the traffic marker should be lighted by day as well as by night. To this end the inside of the casting is equipped with two sets of electric lights, one of 25 watts and two of 10 watts each, making possible a minimum charge for lighting during the day.

The casting has a base diameter of 22 in., weighs 115 lb., and requires no bolts to hold it in place. It is painted in bright yellow weatherproof paint. The lenses may be adapted to any color code.

These illuminated traffic guides are

made in two types. One the "directing" unit is merely a marker for street intersections. The other, or "regulating" unit, carries a panel in which the word "Stop" is made to appear and disappear either automatically or under manual control.

New Gasoline Hammer Drill

A gasoline impact drill of the air hammer type which is self-contained, portable and operated by one man, has recently been developed by the Pennsylvania Gasoline Drill Co., Philadelphia.

The drill, which is named the Somervell, weighs only 70 lb. and although developed originally for drilling rock, is applicable to such work as cutting asphalt pavements, ramming backfill in trenches, breaking concrete, driving spikes and drilling holes in masonry.

The mechanical principle of the gasoline hammer drill, as explained by its manufacturer, combines the action of an air hammer and a gasoline engine in such a manner that the drilling unit has but two working parts, the hammer piston and the fly-wheel assembly. No crankshaft or connecting rod is employed and there is no spring or other yielding member used in the internal construction. No inlet or exhaust valve or cam shafts are used, as the air and gas passages are fixed ports, cut through the solid steel of the cylinder. The drill delivers about 1,800 blows a minute; the fly-wheel which returns the hammer piston on the upward or compression stroke.

Since the drill is a self-contained power unit it is not limited in the radius of its action by the length of an air hose or an electric cable. These drills are already being used by the Philadelphia Electric Co., the Western Union Telegraph Co., and the Edison Electric Illuminating Co., of Boston.

Publications from the Construction Industry

Cranes—INDUSTRIAL WORKS, Bay City, Mich., has published a handsome 161-p. book illustrated with reproductions of photographs and drawings in color on the general subject of cranes. The volume, commemorating the fiftieth anniversary of the company has an introduction in the form of a history of the development of cranes dating back to the primitive methods used by the Egyptians in the construction of the pyramids. The text dealing with the modern machinery manufactured by the company is divided into six sections, dealing with locomotive cranes, locomotive crane accessories including buckets,

grapples, magnets, and draglines, wrecking cranes, special railway equipment in the form of electric and hand-operated tiller and transfer cranes, pile drivers and cranes constructed for export in accordance with special requirements. The text is fully illustrated and an index aids in finding information on any specific type of crane or accessory. There is an interesting series of photographs of railroad wrecks showing the uses of cranes in rescue and repair work. The application of locomotive cranes to a wide variety of industrial and construction uses also is featured. For the user of cranes the volume contains a wealth of information presented in an attractive form.

Rail Steel Reinforcement—FRANKLIN STEEL WORKS, Franklin, Pa., as a member of the Reinforcing Bar Division of the Rail Steel Products Association, is in a position to distribute the booklet "Rail Steel for Concrete Reinforcing," in addition to those companies listed in the notice of this publication appearing on p. 604 of the March 29 issue of this journal.

Concrete Reinforcement—DAVID W. MORROW, Cleveland, Ohio, describes in a 15-p. illustrated pamphlet his patented three-way system of reinforced-concrete flat-slab construction. The system, in comparison with other types of flat-slab design, it is claimed, results in better distribution of panel area which produces a minimum bending moment and secures a shorter length of steel and an equalization of stresses that could not otherwise be obtained.

Excavator and Loader—T. L. SMITH Co., Milwaukee in a 20-p. catalog, describes and illustrates its excavator and loader with particular reference to basement, bank excavating and loading of sand and gravel, stock piles, stripping, and grading of streets and alleys. The loader is a portable gasoline-driven dragline excavator, designed to fill the gap between the large power shovel and the gang of hand-shovel laborers.

Steel Windows—TRUSCON STEEL Co., Detroit, has issued a folio of "Drafting Room Standards" in loose-leaf form showing typical installation details of steel windows of all types. The information is given on 8 x 10½-in. sheets with drawings to scale. These sheets are accompanied by others carrying specifications for all types of windows shown in the drawings. In offering this portfolio of drawings and specifications the company has endeavored to answer in graphic form every question an architect or an engineer might ask about steel windows and industrial steel doors. Details from the loose-leaf sheets may be traced for incorporation on building plans.

Steam Shovel Costs—ERIE STEAM SHOVEL Co., Erie, Pa., has presented in at 71-p. booklet, illustrated, the results of the prize contest it conducted recently to secure data on the performance and upkeep cost of its shovels. The records cover only those shovels which have handled at least 200,000 cu.yd. of material. On this basis the figures cover 48 shovels. The data are segregated according to the kind of material handled—earth, rock, clay, sand and gravel. Particularly interesting is the general summary giving total upkeep figures and averages for all of the 48 shovels included in the survey.

Business Side of Construction

FACTS AND EVENTS THAT AFFECT COST AND VOLUME

Production and Materials Stocks in Eight Cities

Midsummer Slow-Down in Iron, Steel and Cement Output—Lumber Above Normal—Fewer Burned Brick Than Year Ago

Iron and Steel—Pig-iron production during July averaged somewhat over 118,000 gross tons per day as against 122,000, during the preceding month. This rate represents a falling off of nearly 5 per cent from the May average, which was the heaviest recorded in the history of the industry. The July output, however, was slightly heavier than that for April; 2 per cent under the June average and 52 per cent greater than a year ago.

There has been some accumulation of pig-iron and steel ingot reserve stocks. Sheet mill operations continue

half of 1923, totaled 62,226,000 bbl., compared with 48,029,000 during the corresponding period last year. Compared with this time last year, the cement situation is one of increased production and shipments with smaller reserve stocks on hand.

Brick—Report of the Common Brick Manufacturers' Association of America, as of July 1, shows production of new brick for the month, at 128,942,000, with shipments totaling 116,761,000. This leaves the quantity of burned and unburned brick on hand at the plants, approximately the same as for the month

shortage of cement; mills at high production rate. Plenty of common brick and structural steel.

Cincinnati—Scarcity of cement. Plenty of other construction materials.

New Orleans—No reserve stocks of wood paving blocks kept on hand during the last year. Made up as ordered. Stocks of Southern pine much below normal. Plenty of other building materials.

Atlanta—Plenty of brick and lumber. About seven cars of steel structurals; sixty, of lime and seventy-five each of cement and asphalt, on sidings. Sewer pipe and hollow tile deliveries take from four to five days.

New York—Brick scarcity continues, although volume of new business has been considerably reduced. Brickyards, in districts supplying this market, running at full capacity with heavy orders on books. Small reserves of any building materials kept within the city, owing to limited space. Shortage of finishing lime; plenty of common. Small warehouse stocks of steel.

CONDITIONS OF MATERIALS STOCKS IN IMPORTANT CENTERS

Stocks on hand in approximate figures, example: (Cement, Atlanta, about seventy-five cars); time required for delivery M carload lots from mill of "alongside dock," example: (Lumber, New York, four weeks); and stocks on hand in general terms, example: (Brick, Cincinnati, ample).

	San Francisco	Los Angeles	Minneapolis	Detroit	Cincinnati	New Orleans	Atlanta	New York
Sewer pipe	Plenty	Enough to fill requirements	Demand met promptly	Stocks normal	Plenty	Abundance	Del. take 4 to 5 days	Small reserve in city
Cement	Stocks low	Situation improved in month	Ample	No shortage; mills active	Scarcity	Dealers' stocks large; demand ebbing	About 75 cars	Stocks in city small; mill deliveries prompt
Lime	Fairly well supplied	No shortage	Plenty	Supply normal	Sufficient	Plenty	About 60 cars	Shortage of finishing lime; plenty common
Common brick	Stocks in good condition	Supply sufficient	Sufficient	Plenty in local yards	Ample	Enough to fill requirements	Plenty	Scarcity
Hollow tile	Plenty	Requirements being met	Enough	Small reserve; del. take several days	Enough	Ample for "off season"	Del. take 4 to 5 days	Shipments keeping up with demand
Lumber	Heavily stocked	Dealers' stocks heavy	Higher grades in good supply	Yard stocks large	Well stocked	Below normal	Plenty	Del. improved; take 4 weeks from mill
Asphalt	Large native reserve	Well supplied	Ample	Small reserve	Plenty	No market	About 75 cars	Heavy reserves in New Jersey
Structural steel	Bar stocks large; structurals fair; low on rivets	Supply trifle under demand			Slackening in demand; plenty in warehouses		Between 5 and 7 cars	Warehouse stocks not large

at almost 75 per cent of capacity with finishing mills going at a slightly higher rate.

Lumber—Production is proceeding at a rate nearly 7½ per cent above normal, or at about the same rate as prevailed one month ago. Shipments represent 95 per cent and orders 85 per cent of normal production. While there has been no perceptible falling off in output, shipments have been fewer and orders a trifle heavier than a month ago, despite the general downward trend in lumber prices. One year ago, production was 6 per cent below normal, shipments, 90 per cent and orders, 87½ per cent of normal production. The following table shows lumber movements during the four weeks ending July 21, compared with the preceding four weeks.

	Four Weeks Ending—	
	July 21 Ft. B. M.	June 23 Ft. B. M.
Cut.....	1,013,633,602	1,101,749,298
Shipments.....	902,519,673	1,003,405,099
Orders.....	778,785,990	810,722,740

Cement—Reserve stocks, throughout the entire country July 1, amounted to 9,219,000 bbl. as against 10,718,000, for the corresponding period in 1922, according to the Geological Survey. Production totals for the first half of the current year reached 62,320,000 bbl., against 46,918,000, for the same period in 1922. Shipments during the first

preceding. Demand fell off 2 per cent in one month. Stocks of burned brick on hand July 1 were 8 per cent under the amount available for the same period in 1922.

San Francisco—Large stocks of road oils, asphalt, cut nails and Manila rope. Plenty of sewer pipe, clay drain tile and other clay products. Fairly heavy reserves of track supplies, lime, triangle mesh, steel structurals, black steel sheets and wire nails. Dealers' stocks of metal lath, steel bars, brick, tile, lumber and galvanized steel sheets, in good shape. Stocks low, however, on cement, structural rivets and blue annealed steel sheets.

Los Angeles—Enough sewer pipe to fill requirements. Cement situation easier, owing to improvement in mill shipments. No shortage of lime in this district. Dealers' stocks able to take care of steady lumber demand. Structural steel demand slightly in excess of supply. Supplies sufficient in other building materials.

Minneapolis—Stocks of brick, tile, lime and cement are reported ample, with no trouble in supplying demand promptly. Some shortage of low grade lumber is said to exist, a condition obtaining through much of this season, with the higher grades in good supply.

Detroit—Lime, lumber and sewer pipe stocks normal for season. Small reserves of asphalt and hollow tile. No

Construction Equipment Exported

According to figures given out by the Department of Commerce, the following exports of construction equipment, from the United States, occurred during the month of May: 95 concrete mixers costing \$74,530; 747,015 lb. of other construction and road-making equipment, valued at \$85,348; 452,991 lb. of construction equipment not classified, valued at \$97,190; 50 conveyors of the bucket, chain or belt type, valued at \$49,850; 11 steam shovels valued at \$133,677; 59,508 lb. of dredging machinery, valued at \$11,174; 19 cranes, valued at \$77,174; 744 hoists and derricks (except mining), valued at \$68,865.

Japan was the biggest importer of concrete mixers, taking 53 valued at \$32,145; the provinces of Quebec and Ontario, Canada, came next with 20 mixers, at \$14,819. These two Canadian provinces also brought miscellaneous road-making and construction equipment valued at about \$61,000, in addition to 5 steam shovels valued at \$17,000. Other steam shovel exports included one each to Poland, Cuba, Belgian Congo, British South Africa and two to Algeria and Tunis. Four cranes costing \$24,000 were shipped to Canada and two, valued at \$17,000, to Colombia. Japan took about \$14,000 worth of hoists and derricks during May.

Bids Wanted On Big Jobs

Among the projects on which bids are either asked or will soon be called for, in Construction News, pp. 75 to 87, are the following:

Double track steel bridge, Jacksonville, Fla., for Florida East Coast Ry. Co., \$1,800,000.

Hotel, Coney Island, N. Y., for Sea Gate Hotel & Bath Corp., New York, \$1,000,000.

Hospital, Brooklyn, N. Y., for Bikur-Cholin Hospital, \$1,000,000.

Slump in Brick Orders

The slump in building is apparent in the report of the Common Brick Manufacturers Association published Aug. 1 (information as of July 1). Gross orders on books June 1 amounts to 403,691,000 brick as against 395,447,000 July 1. Production of new brick in June was 128,942,000 and shipments were 116,761,000.

The falling off in new business, the report states, is most apparent in some of the centers that have been the busiest

during preceding months. In New York, Cleveland, Detroit, Chicago, and even in Southern California districts, manufacturers, while well stocked with old orders and running at full capacity, have reported that the volume of new business has been considerably reduced. The condition is generally viewed by the manufacturers as seasonal and while all admit that it is possible that the last six months of 1923 will not pile up a volume in new construction equal to the first six months, this still will be a banner year.

Weekly Construction Market

THIS limited price list is published weekly for the purpose of giving current prices on the principal construction materials and of noting important price changes on the

less important materials. Moreover, only the chief cities are quoted.

Valuable suggestions on costs of work can be had by noting actual bidings as reported in our Construction News section.

The first issue of each month carries complete quotations for all construction materials and for the important cities. The last complete list will be found in the issue of Aug. 2; the next, on Sept. 6.

Steel Products:	New York	Atlanta	Dallas	Chicago	Minneapolis	Denver	San Francisco	Seattle	Montreal
Structural shapes, 100 lb.	\$3 64	—\$4 00	\$4 20	\$3 40	\$3.55	\$4.20	\$3.60	\$4.10	\$4.25
Structural rivets, 100 lb.	4.40	—4 75	4 90	3 75	4 25	5.40	5.00	4.75	6.00
Reinforcing bars, $\frac{3}{4}$ in. up, 100 lb.	3 54	—1 00	3 80	3 20	3.45	3.85	+3.65	4.10	4.00
Steel pipe, black, $\frac{3}{4}$ to 6 in. lap, discount,	44%	52%	45%	47%	53-55%	36%	+33 2@42 2%	40%	+47.43
Cast-iron pipe, 6 in. and over, ton....	62.30	—54 00	63.00	60.20	60-60	69.00	62.00	70.00	60.00
Concreting Material:									
Cement without bags, bbl.	2.70@2.80	2 85	2.25	2.20	2.50	2.84	2.63	2.90	2.25
Gravel, $\frac{3}{4}$ in., cu.yd.	—1.75	1 90	+2 38	2.00	+1.85	1.90	2.15	1.25	1.50
Sand, cu.yd.	1 25	1 24	—1 87	2 00	1 25	1.00	1.50	1.25	1.25
Crushed stone, $\frac{3}{4}$ in., cu.yd.	1.75	2 00	+2.83	2.00	2.25	3.50	2.15	3.00	1.90
Miscellaneous:

Common Labor:									
Common labor, union, hour.75	.35				.50@.55	.55		
Common labor, non-union, hour.30	.30@.50	.82 $\frac{1}{2}$	—50@.55	.35@.50	.50	.50@.62 $\frac{1}{2}$.30@.35

Explanation of Prices—Prices are to contractors in carload lots unless other quantities are specified. Increases or decreases from previous quotations are indicated by + or — signs. For steel pipe, the prevailing discount from list price is given; 45-5% means a discount of 45 and 5 per cent. Charge is 15c. per 100 lb. for cutting reinforced steel into 2-ft. lengths or over.

New York quotations delivered, except sand, gravel and crushed stone, alongside dock; common lump lime, in 280-lb. bbl. net, and hydrated lime f.o.b. cars; tile "on trucks"; linseed oil and cast-iron pipe f.o.b. Labor—Concrete laborers' rate, 93c.; building laborers (pick and shovel men) 75c. per hr.

Chicago quotes hydrated lime in 50-lb. bags; common lump lime per 180-lb. net. Lumber delivered on job.

Minneapolis quotes on fir instead of pine.

Brick, sand and hollow tile delivered. Cement on cars. Gravel and crushed stone quoted at pit. We quote on brown lime per 180-lb. net; white is \$1.80 for Kelly Island and \$1.70 for Sheboygan. Common labor not organized.

Denver quotes on fir instead of pine. Cement "on trucks"; gravel and sand at pit; stone on cars; lime, brick, hollow tile and lumber on job. The price is at warehouse. Linseed oil, delivered, in iron bbl. Common lump lime per 180-lb. net.

Atlanta quotes sand, stone and gravel per ton instead of cu.yd. Common lump lime per 180-lb. net.

Dallas quotes lime per 180-lb. bbl. Steel, cement, cast-iron pipe and crushed stone f.o.b. cars, other materials delivered.

San Francisco quotes on Heath tile, size 5 $\frac{1}{2}$ x 8 x 11 $\frac{1}{2}$. Prices are all f.o.b. warehouses except C. I. pipe, which is mill price

plus freight to railway depot at any terminal. Common lump lime per 180-lb. net. Lumber prices are to dealers in yards at San Francisco, for No. 1 fir common.

Seattle quotes on Douglas fir (delivered) instead of pine. Lump finishing lime per 180-lb. net. Hollow building tile delivered. Hydrated lime in paper sacks. Sand and gravel at bunkers.

Montreal quotes on pine lumber. Sand, stone, gravel and lump lime per ton. Cement, lime and tile are delivered; sand, gravel and stone on siding; brick f.o.b. plant; steel and pipe at warehouse. Hollow tile per ft. Cement price is in Canadian funds (the Canadian dollar stands at \$7.75). Bag charge is 80c. per bbl. Discount of 10c. per bbl. for payment within 20 days from date of shipment. Steel pipe per 100 ft. net; 3-in., \$47.43; 6-in., \$119.

Changes Since Last Week

Atlanta reports declines in structural steel, cast-iron pipe, finishing lime, common brick and hollow tile. Dallas reports adjustments in sand and gravel prices and a rise in crushed stone, due to higher labor and freight rates. Minneapolis also quotes an advance in 3-in. gravel, while New York shows a downward trend. Reinforcing bars and steel pipe went up in San Francisco during week.

The iron and steel situation may be briefly outlined as follows: Pig-iron market stronger in several producing centers; inquiries show improvement. Increased activity in steel plate demand. Tank and car construction, as usual taking bulk of output. Plates and

structurals holding firmly at \$2.50 per 100 lb., Pittsburgh. Demand largely for immediate shipments; some makers demanding above \$2.50 for quick deliveries. Improvement in general tone of finished steel market.

The General Contractors' Association of New Orleans is still holding out against the carpenters' unions. About 90 per cent of the vacancies have been filled by strike breakers and no wage concessions are expected from the contractors.

Freight rates on all clay products shipped by rail from various points in the Mississippi valley to New Orleans, will be increased from 2 to 5 per cent per 100-lb., effective Aug. 15.

The general downward trend in prices, particularly of raw materials, reflects the policy of restricted buying which has characterized the market during the last three months.

Lumber and linseed oil lead the decline for the current week; the former reacting to the decrease in demand, and the latter to changes in the flaxseed market. Yellow pine timbers declined \$2 per M. ft. in Chicago; Douglas fir dropped \$1 in Seattle and Minneapolis. Denver also reports a severe drop in fir timbers during the last two weeks. Raw linseed oil declined 3c. in New York and Minneapolis; 4c. in San Francisco and 5c. per gal. in Dallas and Denver.

ENGINEERING NEWS-RECORD

DEVOTED TO CIVIL ENGINEERING
AND CONTRACTING

E. J. MEHREN, Editor
FRANK C. WIGHT, Managing Editor

Volume 91

NEW YORK, AUGUST 16, 1923

Number 7

Real Wages Rising

STATISTICS too often emphasize the average man—who doesn't exist. A low death rate is no comfort to the man who dies; the average income of all the workers in the country does not provide necessities for the group who fall below it. At the same time, such average statistics are the only means for measuring conditions and they are so used. It is interesting, therefore, to find that the National Industrial Conference Board has found that though the cost of living is still high the American wage earner is better off today than during the peak wage period of 1920. Balancing the cost of living against average wages—using 600,000 specific workers—the board finds that the comparative excess of wages over living costs was 18 per cent greater in May, 1923, than in June, 1920. In other words the workman can get more for his daily labor than he could when wages were highest. Specific demands for higher wages will, of course, have to be answered by specific studies of similar nature but the general fact reported here deserves wide appreciation.

Power Act Interpretation Delayed

AS A RESULT of a conference with the Federal Power Commission the Governor's committee of New York officials have advised Governor Smith not to press New York's suit contesting the constitutionality of the Federal Water Power Act. In so doing the committee sets up for its own demolition a straw man of federal usurpation when it says that the commission has been prevailed upon to relinquish the federal government's "proprietary right to share in profits" from power on the border rivers. So far as its record goes, the Federal Power Commission has never claimed such rights. Certainly the power act does not confer them; it merely gives the government the right to say who shall use such waters and to see to it that they are not used to the detriment of navigation or to the continuing rights of the people to get reasonable benefits from the flowing water. The federal law hinges on co-operation between state and nation and the people of the state are deprived of no rights under it. There are, however, some questions as to the extent to which the nation may stretch the interstate commerce clause of the constitution to cover power development and these questions can best be settled by Supreme Court ruling. Until New York or some other state chooses to pursue to a finality an attack on the law its full interpretation will not be assured.

For Safety of Contract Records

EVERY so often there comes a report of a fire which either destroys or seriously threatens necessary records. The latest comes from the Borough of Queens, New York City, where last week a midnight fire in a blueprint department came near destroying the records which control about \$3,000,000 worth of construction

contracts in highway and sewer work in the borough. Such happenings need to be brought to the attention of every one responsible for public work. Not only should duplicate records of every transaction be kept in separate places, but every effort should be made to insure properly fire safe repositories for such records. Building fireproof halls of records after fires have destroyed all previous records comes in the category of locking stable doors after the horse is stolen.

Tarred With the Same Brush

IN THE summer the mills of justice grind slowly; that is the reason little has been heard lately of the government suits and indictments against those who built the cantonments in the early days of the war. In the suits for recovery against the contractors, however, several district court judges have ordered the government to bring a bill of particulars detailing the wastes, which the government charges amounted to from four to seven million dollars at the various camps. Two such bills of particulars recently returned by the Department of Justice are significant, first, because in each the government admits its inability to itemize the wastes which it quite readily totals at seven million dollars and, second, because the detailed wastes, covering several pages of typed manuscript, are identical in the two bills, though one is for a camp in Virginia and the other in South Carolina. This blanketing of a number of different and unrelated men with a common crime is characteristic of the whole procedure of the Department of Justice in the cantonment cases and casts doubt both on the sincerity behind the action and the validity of the cases themselves.

Publicity for Motor Accidents

WHETHER with conscious intent or merely by excellent journalistic instinct a number of metropolitan newspapers have lately taken to grouping each day the increasing grist of automobile accidents. This is one of the best steps toward traffic safety that can be devised. Many motor accidents are unavoidable; they are the inevitable result of our growing traffic congestion. Too many, on the other hand, are due to carelessness, or worse still to an overweening confidence in one's own immunity from accident. Carelessness is an individual and not universal trait, but the assumption that the individual can get away with what spells disaster for others seems to be inherent in the driving of automobiles. Laws and regulations can do little to correct this evil. The best corrective is an accident, but that is somewhat too severe a remedy. The next best thing is continually emphasizing the occurrence of accidents and there are few better ways of doing that than the repetition of grouped accidents in the daily press. Sooner or later this will begin to tell and it will penetrate the consciousness of every automobile driver, provided he or she can read, that crossing occupied rail-

way tracks, passing street cars or other automobiles, speeding around curves and other common but foolhardy driving stunts are more than ordinarily hazardous performances. Perhaps every driver will become as foresighted as that one whose passenger said when they were approaching a railway track that he was afraid the train would beat them to the crossing. "That's all right," said the driver, "What I'm afraid of is a tie."

Snow Removal and Road Damages

SYSTEMATIC study of damages to paved roads from snowfall and removal of snow has not proceeded far. Observation indicates, however, that the effects of snow are more varied and their causes more complex than first assumptions would indicate. There is more for consideration than normal frost action. Frost damages are not novelties to highway engineers but there have come about conditions modifying frost action which are in a measure new. Year-around traffic, heavy loads and snow removal, which formerly did not have to be considered, are now common conditions. Altogether there is before highway engineers a largely new problem of road maintenance as affected by snowfall.

Any conclusions which can at the moment be drawn of the possible damaging effect on paved roads of snowfall and snow removal are necessarily indefinite, if not wholly speculative. Winter damage is evident whether we consider the records of Massachusetts and Connecticut or those of Wisconsin and Minnesota. It is evident too that heavy truck traffic has increased the destruction of road surfaces affected by frost. Again the injuries are different when the road is kept clear of snow and when it is left untouched or is only partially cleared. This is about as far as one can arrive at present. Even this slim array of conclusions, however, indicates a situation which is worth investigation.

Winter freight haulage by motor truck and winter passenger transportation by motor bus must be accepted as certainties. They will moreover extend far beyond thickly populated regions though naturally they will be most intensive where cities and towns abound and industry is intensive. There are today active bus lines in the mining regions of northern Minnesota and Michigan and all through the rural regions of the Middle and Far West as well as in Connecticut and Massachusetts. They are maintaining regular winter schedules. Truck transportation is equally as general, where paved roads exist, though it is customarily less regular.

Where this winter traffic prevails the road will be cleared of snow to provide for its movement. If the clearing is not done by state or county maintenance departments it will be done by the carriers themselves. Indeed carriers generally are doing it. The bus transportation companies today in every state in the North have better organizations for fighting snow and more costly and powerful units of equipment for snow removal, within the fields of their activities, than have most public roads maintenance departments.

Snow removal means different things in different instances. It means completely cleaning the full width of the pavement and also cleaning a path along the center of the paved surface and again only the removal of depth enough to allow traffic to get through. If carriers do the clearing they will, unless they are controlled, carry removal only far enough to serve their purposes. If a single-track path is enough for their

purposes this is all they will keep open. If they can maintain schedules with a mat of snow and ice covering the pavement they will not remove this mat. The significance of these facts is, quite certainly, that different damages to road surfaces may be expected according to the practice of snow removal.

If only a single track path in the middle of the road is kept clear, observation indicates that two things happen, (1) Vehicles follow the same tracks and wear is concentrated in ruts and (2) the subgrade under the exposed center zone freezes differently than under the pavement flanks and on the road shoulders which are covered with piles of snow. The second condition is emphasized when there is a heavy fall of snow before the ground is frozen deeply as was the case in some of the New England states last winter. The result is a deep frost crust under the middle of the pavement and shallower frost crusts under the sides and when the frost goes out in the spring the pavement is hung up on a center ridge and under heavy traffic breaks down at the sides and cracks along the crown. If all the snow is not removed down to the pavement, whether it is cleaned full width or not, the covering mat becomes rutted down to the pavement and it is worn in grooves.

These then are some of the indications of the bearing which snow removal may have on damages to paved roads carrying heavy traffic in winter. It is obvious that they are far from exhausting the possibilities. They are, however, enough to demonstrate that a study of road damages from snowfall and removal of snow is a profitable undertaking for highway engineers. Indeed the coming winter, it is hoped, should see it carried well forward. Until the effects of snow removal on damages to paved roads are learned, correct practices of removing snow cannot be established, and they are important if commercial truck and bus lines are to continue their present snow-cleaning operations.

Sewage-Works Progress at Indianapolis

INDIANAPOLIS is contributing materially to the development of sewage-works practice by the 50-m.g.d. plant described elsewhere in this issue. In point of size the plant will be several times the largest in the world when it goes into operation, although soon afterwards it will be surpassed in capacity by the Milwaukee plant and still later by Chicago's large projected plant.

At Indianapolis, Mr. Hurd states, a variety of local conditions favored the activated-sludge process. Some of these made a considerable degree of pre-treatment of the sewage seem desirable before activation. This led to the adoption of the interesting revolving barrel screens, sedimentation tanks, and sludge concentrators which are features of the Indianapolis plant. Sewage-works engineers will await the results of this pre-treatment in order to see whether it may be advantageous elsewhere to lighten the burden on the activated-sludge plant. The working of this type of screens, too, is a matter of wide general interest, for present indications are that fine screening will come into much more extended use than formerly, either where it alone is sufficient for a time or where lessening the load on some more thorough process of treatment is considered advisable. Adherence to compressed air instead of adopting mechanical agitation for activation, although the latter was tested at Indianapolis, is in line with American practice, but it is significant to note that

the filtros plates are set at one side instead of all the way across the bottom of each channel of the aeration tanks, thus giving a spiral motion to the air and sewage.

Dehydration, at Indianapolis and elsewhere, seems to be the subject on which further light is most needed. This need is greater with activated than with other types of sludge, partly because of the peculiar character of this sludge, but largely because the hoped-for end is the production of a commercial fertilizer base, of unusual promise because of the high nitrogen content of the activated sludge. Unlike Milwaukee, Indianapolis will not make use of acid conditioning in its sludge dehydration process—another example of divergence in practice due to local conditions and perhaps somewhat to variations in personal judgment.

Altogether, the Indianapolis plant, both in itself and as a contribution to the development of sewage treatment in general and of the activated sludge process in particular is most commendable.

Engineers for Bridges

FOR an engineer to argue the superiority of the engineer over the architect as a builder of bridges is most difficult. Called upon to do so he feels just as a doctor would who had to defend his profession's right to tend the sick or as would a mathematician when confronted with the statement that two and two make five. It is one of those obvious things that ought never to be questioned. And yet every so often it is questioned and in such a way that engineers in person and in groups are required to restate the obvious. Such an occasion has now arisen in Pittsburgh.

Through a combination of circumstances the county commissioners there are now being importuned to turn over to architects the control of three new and large bridges required by federal order. The circumstances include a doubtless well meaning but misdirected campaign on the part of an eminent Pittsburgh artist to insure, by architectural control, the proper artistic co-ordination of the three bridges with the future development of the city and the efforts of the local chapter of the American Institute of Architects to capitalize this campaign to the advantage of their own profession. In so doing they have repudiated the report of one of their own committees, which collaborating with a local engineering committee recommended a workable scheme for engineering control of the bridges with proper architectural advice, and have gone so far as to submit to the commissioners a list of architects who would be willing to undertake the design and construction of these bridges at a 6 per cent fee. It is possibly only incidental that this list consists not of a selection of architects necessarily qualified for the work, but of those architects who have offered their services for it.

The movement in Pittsburgh to develop the new bridges as commanding elements in the general picture of the city will meet hearty welcome on the part of all engineers. Too frequently in the past the prevailing attitude, forced more generally than not upon the engineer by the public bodies in charge of bridges, has been that whatever would do for the moment's needs at lowest cost was the proper bridge to build. The result was the erection in too many cases of impoverished structures having short life and subject to rapid obsolescence and depreciation. No one knows this bet-

ter than the engineer. No one realizes better the impoverished art which results from such lowered standards of design. Fortunately, however, the engineering profession is so concerned with safety in structures that in most cases it has been able to resist the low ideal of cheapness and to insist that every bridge shall be the most perfect adaptation of materials to the needs of the type and the service.

Those who are urging the architect's predominance in bridge design, however, seem to consider that safety is something which can be readily obtained by employed experts and that the crowning necessity of a bridge is that it shall be beautiful. The engineer's answer to that is first, that it is essentially vicious that the safety of the public should be made subordinate to the esthetic sense and second, that true beauty results from the proper adaptation of the material to the service and that the engineer who must be responsible for that adaptation can better insure that beauty than can the one whose primary desire is to attain it.

Further than that, the issue is a practical one, for the engineer can point to the many bridge structures which adorn our waterways and cities which achieve true beauty by true adaptation of the material to the service. He is sometimes astonished at the calm assumption frequently made that everything that the engineer builds is inherently ugly and everything that the architect builds is inherently beautiful. So general a rule cannot be demonstrated. The streets of our cities, for whose adornment the architect is solely responsible, are its refutation. One recalls, for instance, the horrible example of the almost interlocking Singer Building and City Investment Building on lower Broadway, New York, built some fifteen years ago by two of the leading architects of their time, built simultaneously, each with the knowledge that the other was being built and yet designed with apparent studied effort for discord between the two in line and tone. Taking the country over it is to be questioned whether the buildings erected by our greatest architects are more beautiful, more adapted to their purpose and to their location, than are the bridges built by our greatest engineers. There are many ugly bridges. There are, on the other hand, many ugly buildings. Appropriateness of a bridge design is a matter of the individual and not of the profession. The question of its safety is distinctly a question of the profession which has it in charge.

It should be farthest from any engineer's efforts to dissociate the competent architect from the design of a bridge. Nor should that association be confined merely to superficial decoration, for in that direction lies the greatest artistic danger. The fact remains that the safety of the bridge should be the prime consideration and for that safety the engineer alone should be responsible, which means that he should have primary control. Having that control he may have to work with him in almost co-ordinate responsibility for outline and general appearance an architect trained in the niceties of adaptation of line and tone. Such collaboration is by no means uncommon, and the resulting structures have been most successful. It can be worked out in Pittsburgh, if the County Commissioners are not stampeded into unwise action by an exaggerated conception of the architect's ability and functions and an insufficient appreciation of the importance of safety in public structures.

Concrete Caissons Sunk in Place for Wharf and Seawall

Seawall for China Basin Terminal on San Francisco Bay Consists of Caissons 57 Ft. Deep Connected by Concrete Arches Placed in Precast Sections

BY FRANK G. WHITE

Chief Engineer, California Board of State Harbor Commissioners

THE CHINA BASIN terminal, which is under construction on the San Francisco waterfront by the Board of City Harbor Commissioners, consists of a combined transit shed and warehouse located on submerged land about one mile south of the Ferry Building. The terminal building will be 812 ft. long and six stories high, supported on a pile foundation which is protected by a concrete seawall. The seawall consists essentially of a series of precast reinforced-concrete caissons set as piers and between which the openings are closed by curved curtain walls. The caissons, which extend to a depth of 57 ft. below the deck of the wharf,

The concrete mix consisted of 1 part of cement to 5 parts of graded aggregate. Concreting was done in two operations; the sides upon which the caissons rested were first poured and after these had set up the inside and outside forms were installed, the remainder of the reinforcing was placed, and the sides, partitions and top were poured. Special care was taken in preparing the contact surfaces and no difficulty was experienced in making watertight joints. The lower ends of the caissons were closed by reinforced-concrete bulkheads in which the reinforcing bars did not project into the side walls or partitions. The upper ends were closed by wooden bulkheads bolted to position from the outside and made tight by asphalt joints.

The concrete in the caissons was allowed to set for at least 28 days before they were launched. After launching they were towed to the site and set in holes excavated to depths of 6 to 18 ft. in the hardpan. In excavating these holes the contractor used cartridges made up of sections of old boiler tubing, 3 to 5 ft. in length. After being loaded each cartridge was wedged into a hole in the bottom of a heavy steel spud

FIG. 1—LAUNCHING CAISSONS FROM CASTING YARD

Caissons were started down the ways by block and tackle from a hoisting engine. Note temporary concrete bulkhead just inside bottom, which was broken out after caissons were placed.

were cast in a nearby yard, floated to place and sunk to footings prepared under the inspection of a diver. Outside this seawall dredging is to be carried to a depth of 36 ft. below mean lower low tide.

The terminal is located on the northerly side of a small indentation of the shore line known as China Basin, with a hard bottom of cemented sand and clay at a depth of 22 to 40 ft. below mean lower low tide. Overlying this hard bottom is a blanket of soft mud from 12 to 25 ft. in thickness and from borings and soundings it was decided that piles could be driven from 12 to 25 ft. into the sand and clay substrata. In order to add to the stability of the foundation, before any piles were driven, this mud was dredged out and replaced with clean sand. The dredging was done by the commission's own equipment, using a 31-cu.yd. clam-shell bucket dredge and 250-cu.yd. bottom-dump scows.

The caissons, 40 in number, were cast on the side on wooden launching cradles, the casting yard being laid out to accommodate 20 caissons at a time. The cradles were supported on skidways, along which they were moved by hoisting engines to a position in front of the launching ways which were located at one corner of the yard. The caissons were built with three compartments, the outside walls being 7 in. thick and the partitions 6 in. in thickness.

FIG. 2—FILLING AND SINKING CAISSON TO POSITION

At stage shown, the weight of the caisson, partly filled with water, is carried by the pile driver. Later the weight was transferred to four chain blocks on the traveler at the right.

which was dropped through the water driving the charge into the hard bottom. After being shot the material was removed by an orange peel bucket operated from a floating derrick. This method of loosening the bottom proved to be an inexpensive means of doing what would otherwise have been costly. The contractor was expressly forbidden, by the specifications, to follow the cheaper method of dredging a channel for the row of caissons because it was desired to gain the advantage

FIG. 3—PLAN OF THREE-COMPARTMENT CAISSON

of the side support that could be expected from putting the caissons in holes. The excavation was carried approximately 12 in. below grade, the holes being gaged by lowering a templet made of steel angles. A diver inspected each hole as the templet was lowered, trimmed off any irregularities or high spots, and supervised the placing of the crushed rock which was used to level up the bottom and bring it to grade.

The setting of the caissons was done by the combined use of a floating pile driver and a traveler mounted on pile falsework. The traveler was of timber supported on 18 double-flanged wheels running on three rails, the gage of the outside rails being 15 ft. This traveler was also used for placing the crushed rock in the bottoms of the holes, hoppers being constructed on top of the frame from which the rock was distributed through a jointed pipe. The caisson to be set was towed to position with the lower end toward the hole in which it was to be placed.

By pumping water into one side compartment and taking a lift with the pile driver on U-bolts set in the top in line with the opposite partition, the caisson was turned on edge. The lower end was then placed between bents of the falsework and the filling and hoisting continued until it was suspended in a vertical position. The load was then transferred to four chain blocks on the traveler by means of which the setting with the faces truly vertical and to line could be very closely controlled. When set in final position the caissons were

FIG. 5—TRAVELER SETTING CAISSONS IN FINAL POSITION

Traveler on falsework at the left carried crushed rock hoppers and also chain blocks for placing caissons. At right steam hammer is driving piles through bottoms of caisson already set.

14.5 ft. apart with the 20-ft. sides at right angles to the axis of the wall. The average weight of the caissons was approximately 150 tons, but the displacement was so accurately controlled by water ballast that they were readily placed by four 5-ton chain blocks.

The spaces between the caissons and the sides of the holes in which they were set were filled with crushed

rock thoroughly tamped into place, using a heavy steel tamping bar handled by a floating derrick. Water was then admitted to the caisson. If any unequal settlement occurred bents lifted the lower side of the caisson by raising timbers carrying chains to the caisson U-bolts. With the jacks thus holding the caissons plumb, crushed rock was dumped and tamped around the lower side until the caisson stood plumb without the aid of jacks. When firmly bedded in final position the lower bulkheads were broken out and the concrete was thoroughly pulverized by the use of the steel chisel and tamping bar already referred to. By means of a follower a pile driver mounted on the falsework then drove fifteen piles in the bottom of each compartment, securing in all cases a penetration of 12 to 20 ft.

The caissons were sealed by depositing about 10 ft. of tremie concrete around and over the heads of the fifteen piles, which were left projecting approximately 8 ft. into the bottom. The tremie rig was equipped with a tower and hoisting engine for handling the 18-in. pipe and with three concrete hoppers, each of sufficient capacity to permit of filling a compartment to the required depth with one charge. After this concrete had set, the caissons were unwatered, the laitance and separated materials, having a thickness of 1 to 2 ft., were removed and the pouring of concrete used to fill the caissons was completed. The concrete used in the tremie work was 1:4 and in the remainder of the caisson fill, 1:9, the aggregate being proportional in both cases for maximum density.

The reinforced-concrete curtain walls closing the spaces between the caissons are arches 1 ft. in thickness. The curve is an arc of a circle and each section comprises a quadrant, i.e., has a central angle of 90 deg. Three sections of these curtain walls were used to complete the required height of 34 to 40 ft. The curtain walls were cast in a vertical position on barges, the forms being set for complete circles with partitions at the quarter points to separate the four quadrants. They were cast with tongue-and-groove horizontal joints. The arches were set with the aid of a floating pile driver, wooden guides being used to hold the curtain wall tight against the bearing surface of the caisson.

After the three sections required to make a complete

FIG. 4—PLAN AND ELEVATION OF FOUNDATION AND SEAWALL

FIG. 7—TYPICAL SECTION THROUGH SEAWALL AND FOUNDATION

closure between adjacent caissons were in position, the vertical groove on either side of the curtain wall was filled with grout. To prevent the grout from escaping through the cracks along this groove, it was deposited inside a canvas bag or "stocking." When the sections of the curtain wall were all placed, a 2-in. iron pipe was lowered down the groove to make sure it was clear. The pipe was then withdrawn, the canvas "stocking" was slipped over it, and pipe and "stocking" were lowered into the groove. The upper end of the pipe was connected with a hopper containing grout, hopper and pipe being slung from hoisting tackle on the pile driver leads. When pipe and stocking had been lowered to

supported on clusters of piles which were driven through the sand fill and into the underlying hardpan. Combined with these footings are a series of heavy reinforced-concrete ties, 3 ft. deep and 8 ft. wide, which serve to anchor the tops of the caissons to the heads of the piles across the full width of the building. Steel tie rods were used, hooked into notches provided in the second lift of the caisson fill, and the last lift of the caisson fill was poured with the footing.

The first floor over the outer half of the building is of flat slab construction and is supported by the column footing; the remainder or inner portion of the floor is laid directly on the sand fill. The floor or deck of the wharf along the channel consists of a series of arches extending from caisson to caisson and designed to carry two railroad tracks.

Past Year Shows Increase in Federal Water-Power Permits

The Federal Power Commission closed its fiscal year on June 30 with a total of 425 applications for preliminary permits and power development licenses. One hundred and four of these were received during the past year, 51 of which were applications for preliminary permits for investigatory purposes. The remaining 53 were for licenses covering construction, and included 17 major projects, 13 projects of less than 100 hp., and 23 transmission lines. During the three years of its existence the commission has authorized a total of 97 preliminary permits and 105 licenses. Of the 42 major projects included in these licenses, all but eight are either constructed or under construction, and all but three or four will go ahead within the time limit of the license. With respect to the preliminary permits, however, the progress has not been so marked. Only five of the 97 issued have been followed up with applications for licenses, twelve have been cancelled, and the others have been extended to the full time limit of three years. This time limit will expire on several important projects next March. Among them is the White River project of the Dixie Power Co. in Arkansas, the 350,000-hp. development of the Washington Irrigation & Development Co. at Priest Rapids on the Colorado River, and the proposed Niagara Gorge development of the Lower Niagara River Power & Water Supply Co., a subsidiary of the Niagara, Lockport & Ontario Co. This latter development is being held up at present by the failure of the State of New York to grant the company the necessary permit.

FIG. 6—LOWERING TO PLACE SECTION OF CURVED CURTAIN WALL

These sections 12 ft. long and weighing about 16 tons were delivered on barges and placed with tackle from the driver leads.

the bottom of the groove, grout was admitted to the pipe and as the stocking filled, the pipe and hopper were lifted. This proved to be a very effective means of making a tight joint between curtain and caisson. After the curtain walls were grouted a rock fill was placed against the inside face and between the caissons on the outside of the curtain wall.

The building foundation consists of concrete footing

Variations in Floor Load Requirements of Building Laws

IN THE STUDY of building law requirements now in progress by a committee of the U. S. Department of Commerce, the wide variation in ordinance requirements as to the loads for which floors must be designed has had special attention. The committee has also endeavored to collect such scanty data as exist concerning actual loads which occur or may be expected in different classes of occupancy, and in this connection brought about the conduct of a special set of load weighings in the Equitable Building as reported in *Engineering News-Record* of March 29, p. 584. Its work requires

Gassing of Enginemen in Railway Tunnels

ACCIDENTS to locomotive crews in tunnels on the Union Pacific R.R., due to pollution of the air by gases from the engines, has led to an investigation by the U. S. Bureau of Mines. A report by S. P. Kinney, assistant metallurgical chemist of the bureau, states that in thirty-four out of forty trips through the tunnels carbon monoxide was found in the air; twenty-nine tests showed 0.01 to 0.20 per cent and five showed 0.21 to 0.35 per cent. In a normal running time of six minutes for 2,000-ton trains through the Aspen tunnel, 5,941 ft. long, the cab temperatures reach 114 and 111 deg. F. on the dry and wet bulb thermometers respectively,

much further collection of data on actual loads, however, and the committee is anxious to enlist the co-operation of technical organizations and individuals throughout the country in obtaining such data. To exhibit the unsatisfactory present conditions the committee has compiled a table of the floor loads specified for building design by 109 city building laws. A summary of the table is reproduced herewith.

As the table shows, first floors of dwelling houses must be designed under the rules of one city for 25 lb. per square foot, under those of another for 100 lb. per square foot, and according to the most common building-law requirement for a load of 50 to 60 lb. per square foot. The loading for assembly hall floors ranges from 70 lb. to 150 lb. per square foot; that for school rooms from 40 to 150 lb. per square foot; that for public garages from 50 to 250 lb. per square foot, and that for the ward rooms of hospitals from 30 to 150 lb. per square foot.

The committee believes that such variations correspond to no essential differences of practice or of conditions in different parts of the country, and that they largely arise from actual ignorance of the loadings to be expected. The collection of loading data should, therefore, prove a preliminary toward the elimination of unnecessary and wasteful diversity of practice.

with a relative humidity of 90 per cent. The maximum temperatures recorded were 136 and 124 deg. respectively. Actual running time was ranged 4½ to 25 min.

It was found that asphyxiation due to carbon monoxide and exhaustion due to high temperature and humidity are the main causes of the accidents in these tunnels. Pocket respirators and other types of gas masks packed with soda-lime-charcoal mixtures afforded protection against smoke and sulphurous gases, and carbon-monoxide masks against all gases encountered, though there was some discomfort in wearing gas masks in an atmosphere of high temperature and humidity.

Air from the train pipe of the brake system showed no carbon monoxide and is cooler than the cab air. It is recommended that the engines carry respirators which can be attached to the train pipe, giving a supply of air sufficient for ten minutes, or thirty minutes in combination with the air-brake tanks. Deflectors on the smokestacks, which deflect the smoke and gases away from the cab, are reported to be efficient in reducing cab temperatures 20 to 30 deg. As carbon-monoxide poisoning requires special treatment, it is suggested that engine crews, signal repair men and men working in the vicinity of the tunnels should be instructed in first-aid treatment for such cases. It would be advisable to shorten the time of passage through long tunnels.

Missouri

Speeding Construction

Missouri has under way one of the largest road building programs of any state in the Union. In developing its work it has laid down the principle that highway improvement is a process. Progressive construction and full-system maintenance, as practiced in other states, are included in highway improvement as a process, but in Missouri the thought is carried farther to a definite plan of popular education. "Highway development is a process" has been made virtually the official slogan of the state highway administration.

Missouri's present large road building program first assumed definite shape in 1921 when the state legislature in a special session designated the 7,630-mile state road system, and the people by popular vote authorized the sale of \$60,000,000 worth of bonds for the purpose of financing the construction of these state roads.

It is a construction and maintenance task being rapidly accomplished that we have to consider at present. On April 1, 1921, there had been completed 141 miles of the roads comprising the state system, of which 7 miles were of graded earth. Stating this result in terms of the entire system there were then 1.75 per cent of the system surfaced and .094 per cent of the remaining portion of the system graded preparatory to surfacing. On April 1, 1923, there had been completed 1,448 miles of state roads, of which 775 miles were of graded earth. Again expressing these results as percentages of the whole, there are at this time 8.885 per cent of the system hard surfaced and 11 per cent of the remainder graded preparatory to surfacing.

On April 1, 1921, the rate of progress was 1.2 miles of graded earth per annum and 72 miles of surfacing per annum. On April 1, 1922, the rate for graded earth had increased to 248 miles per annum and the rate for surfacing had dropped to 60 miles per annum. On April 1, 1923, the rate of progress had reached the figure of 702 miles of graded earth per annum and 94 miles of surfaced highways per annum. Production of graded earth roads increased faster than surfaced roads.

There are at this time 429 separate road projects under way, totaling nearly \$29,000,000 worth of work under contract, calling for the grading of 987 miles of earth road and for the surfacing of 1,006 miles of paved highways. The funds available for further lettings in 1923 consist of \$1,632,000 of federal-aid and \$4,900,000 of bond issue money. There are now 261 miles of primary roads under contract at a price of \$6,306,650, averaging \$24,200 per mile. There are also under contract 413 miles of secondary roads to be built out of

bond issue money, aggregating a total cost of \$4,199,110 or about \$10,150 per mile. Bond issue projects are under way all over the state with the exception of 23 counties. There have already been established in 86 counties county-maintenance organizations headed by a county-maintenance superintendent who reports to the division maintenance engineer. Contracts are being made for maintenance work with local parties, special road districts and county courts to cover principally the dragging of roads at a price of \$40 to \$50 per mile per annum. The county maintenance superintendent is furnished with a Ford roadster or a Ford truck and is supplied with picks, shovels and other small tools which are on hand as part of the War Department equipment allotted to the state. Also one or two tractors are being distributed to each county for use in the maintenance of its state roads, such tractors being a part of the above mentioned War Department equipment. A further impetus to maintenance operations will be given by the new equipment for which orders have been placed. This equipment includes 106 graders of varying sizes and weights, 239 drags, 123 road plows and 219 scrapers.

Out of the necessities of the work there has grown up the organization indicated on the adjoining chart, Fig. 7. In order to relieve the executive head of the large burden of routine operations, much of the detail of the administrative work of the department has been subdivided and allotted to the following bureaus: (1) Bureau of Surveys and Plans; (2) Bureau of Bridges; (3) Bureau of Construction; (4) Bureau of Maintenance and (5) Bureau of Audits.

Each bureau is in the charge of a bureau head, who is in close contact with the chief engineer. Weekly reports by each bureau chief are made to the chief engineer. These reports are bound together and supplemented by a report of the chief engineer and then transmitted to the commission. In this manner each member of the commission is regularly informed of the operations of the department during the period between meetings of the commission.

Speed in getting a large construction program under way as described, in establishing maintenance and in creating a direction organization is the salient characteristic of the moment of road development in Missouri. With maintenance proceeding, road grade is being produced first and then surfaced road. Two types of paved road present unusual practice; one is bituminous surface on sledged stone base and one is base of 1:3:5 concrete used as a road until traffic warrants addition of the bituminous surfacing. An outstanding structural feature of Missouri road work is

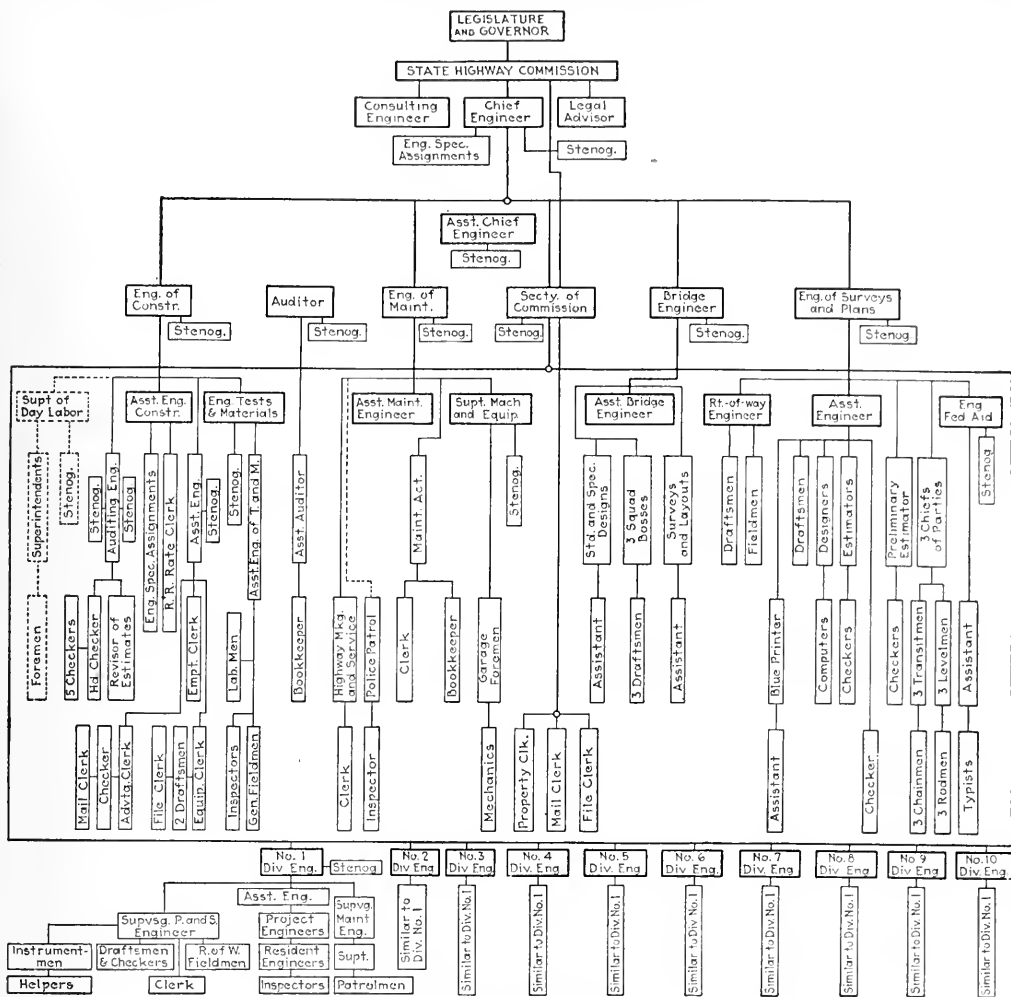

FIG. 7—MISSOURI HIGHWAY COMMISSION ORGANIZATION CHART

bridge building. Missouri is a state of many streams and notably of one great stream, the Missouri River, dividing the state into two parts. Present highway work includes no less than four Missouri River bridges, with steel structures, respectively 2,665 ft., 1,524 ft., 1,955 ft., and 3,071 ft. long, to cost \$2,847,212.

Recognition of the fact that successful highway administration is in part the task of holding the faith of the people in highway improvement is the vital spark of Missouri highway department practice. There is no state of the group, that has been considered in this series of articles, in which the people are being so candidly and continuously told what is being done and why, what the fundamental processes of highway development are, what excessive speed and overloading signify and what the part of the public is in managing its great highway property. "Tell the people" is almost the cardinal commandment of the road administration decalogue.

Vermont Reorganizes Its Government

The administrative departments of the State of Vermont have been consolidated so as to replace over twenty boards, commissions, officers and agencies by seven departments. Of these the departments of highways, public service, public health, and education are placed under small boards, while the finance, public welfare, and agricultural departments have a single head. The Department of Public Service includes utility regulation, weights and measures, regulation of labor disputes, and the general regulation of the industries of the state. The Department of Finance has charge of budget making, banking and insurance, taxation, accounting and purchasing. All the department heads and commission members are appointed by the governor. The tenure of office for the single commissioners is the same as that of the governor, but the terms of members of the boards, in the four departments named, expired at different times.

Design Features of the Indianapolis Activated-Sludge Plant

Circulating Aeration Effected by Deflecting Baffles Giving 6-Mile Travel at Rate of 2 Ft. per Second—
Rapid Removal of Sludge in Deep Tanks with Settling Cones Near Inlets

BY CHARLES H. HURD

Consulting Engineer, Sanitary District of Indianapolis, Ind.

SEWAGE treatment at Indianapolis will be a combined system of partial clarification by fine screens and rapid settling followed by an activated-sludge process. The primary treatment portion of the plant was described in *Engineering News-Record*, March 23, 1922, p. 484. This article deals with the activated-sludge plant and the bearing which the experiments at the testing station of the last year have had on the design. In general it has been found that the rapid and early removal of suspended organic solids is a large factor in the aeration process and that a circulating aeration induced and

CONCENTRATE THICKENER TANKS FOR CONTINUOUS
SLUDGE REMOVAL

The sludge removal mechanism consists of chain-driven flights which scrape the sludge toward concentration cones at the inlet ends. The framework to support the upper returning flights will be placed near the top of sloping sides in the recesses shown.

speeded up by proper baffling gives better results and at greatly reduced cost than the conventional types of air plate distribution. Deep sludge settling tanks with the cones placed close to the inlets are preferred. Present methods of sludge dehydration procedure leave so much to be desired that final designs and choice of apparatus will be fully developed under actual working conditions.

From sewer gagings it has been estimated that the average dry-weather flow for the Sanitary District of Indianapolis will be 50 m.g.d. for 1930, 64 in 1940 and 72 m.g.d. in 1950, with maximum day flows at rates of 75, 96 and 108 m.g.d. respectively. In the plant design, all structures which are placed below ground and which cannot be easily extended or expanded are constructed for the calculated 1950 condition; all structures which may be more readily extended or expanded, and in which there would not be considerable economic loss due to expansion, are built for the assumed capacities for the 1930 condition.

Rapid Sedimentation Tanks—As was described in the article mentioned, the concentrate thickener tanks perform a most important function. Briefly, these tanks are four in number, 15 ft. wide, 120 ft. long and 12 ft. deep. They are constructed with sloping sides at the bottom and provided with sludge removal mechanism and concentration cones at the inlet end. In operation, the heavy sewage containing the suspended solids, which have been retained by the fine screen filters, flows by gravity directly to the inlet of the tanks. In

this operation it is important not to break up the individual masses or to separate the adhered colloids from the solids in suspension. The four tanks have a volumetric capacity of 500,000 gal. and when operating at a rate equal to 30 per cent of the total flow to the screens (equivalent to 15 m.g.d. for the 1930 conditions) will have a subsidence period of 48 minutes. The velocity of flow through the tanks corresponding to this rate is 2.5 ft. per minute. The sludge removal flights operate at a velocity of from 5 to 7.5 ft. per minute. The returning flights which pass through the sewage about 3 ft. from the bottom, move in the same direction as the sewage flow. In the preliminary design, it was considered advisable to operate the flights at the same velocity as the flow of sewage. Subsequent tests, however, have proved this to be unnecessary. The high efficiency of these tanks is undoubtedly due to the freshness of the sewage treated and the means of conducting the sewage through the screen channels and connecting conduits without agitation. The high rate can be accounted for by the absolute control and the uniform and continuous flow from one end of the tank to the other. This complete displacement prevents counter or conventional currents resulting from short circulating or changes of temperature. Two 3-hp. motors are provided for operating the four tanks.

Activated-Sludge Development—Experience has shown that in the activated-sludge process the rate of treatment depends largely on the freshness of the sewage and the total organic solids contained. With Indianapolis sewage the aeration rate is governed largely by the removal of organic solids in the thickener tanks. During the year 1922 experiments were continued at the demonstration plant to determine the most economical operating rate as well as the quantity of air necessary to produce the required stability. Five aeration tanks were used for this purpose, all of which were 15 ft. deep. Four of these tanks were circular in plan and 12 ft. in diameter. The fifth tank was originally constructed as a section of a proposed full size unit and was 15x15 ft. in elevation and 5 ft. long.

Subsequent to tests that were made on screened and unscreened sewage and a demonstration of mechanical agitation, Tank 1 was continued as a control unit with the conventional arrangement of diffuser plates and with a total plate area 25 per cent of the tank area. Tanks 2, 3 and 4 were equipped with different systems of vertical baffling and diffuser plates, with 10 to 12 per cent diffuser area, set eccentrically in the bottom to give over-and-over circulation in the tanks. Tank 5, designated at the plant as the "circulating tank," contained six diffuser plates independently controlled and set in two rows within 30 in. of one side. Five plates were in operation during the greater part of the demonstration runs, which gave a 6.66 per cent diffuser area. Throughout these tests on the tanks above described the average rate of operation per acre was 25 m.g.d. and the use of air varied from 0.5 to 1.25 cu.ft. per gallon of sewage. The composite results of these tests

TRANSLATION OF AIR BUBBLES IN GLASS CIRCULATING TANK

Water velocity at 2 ft. per second sweeps across bottom of tank and deflects incoming air rising from air plate to the left. Baffles at corners give the rotary motion which in a large tank (of which this is a miniature transverse cross-section) would be a spiral, with the pitch determined by the detention period and the length.

indicated that a stable effluent could be obtained at the above rate of operation with an approximate use of 1 cu.ft. of air per gallon of sewage treated.

As a summary of the experimental work on aeration at the demonstration plant during the past two years and a comparison of the types of tanks used it may be stated that the most satisfactory operation was obtained by the use of the rapid circulating tank. This tank was operated in parallel with the conventional types and followed experiments on mechanical agitation. The conventional tank produced a stable effluent, but required

a slightly greater quantity of air than the circulating tank to keep the sludge in suspension. The mechanically agitated tank was not consistent and dependable in operation and did not produce a good quality of sludge nor a satisfactory effluent.

Tests on Circulation—Following the comparative study of the three types or methods of aeration, extended experiments were made to determine the best and most economic system of deflecting baffles for the circulating tank. The greater number of these experiments were made with air supplied at the rate of 0.5 cu.ft. of air per gallon of sewage and the operating rate at 20 m.g. per acre. Generally speaking, the use of deflecting baffles increased in the circulating velocity almost proportionally to the area up to about one-fourth the distance across the tank. The angle and total deflector area which seemed most economical in construction and service is shown in the sectional elevation of the aeration plant. It should be noted that this method of baffling increased the circulating velocity practically 100 per cent above the velocity produced without baffles.

The preliminary design of the aeration plant provided for units with circulating channels 15 ft. wide and 15 ft.

FINE SCREEN CLARIFIERS IN PUMPING STATION

Rotary screens are revolved by vertical motor at left through a jack shaft to which any one screen of three in a set can be connected by clutch.

deep. While the plans were being developed more extended experiments were made by increasing the width of the circulating tank section to 20, 25 and 30 ft. The purpose of these experiments was to determine the greatest width which would be practicable (maintaining sufficient bottom velocities to prevent deposition of sludge), in order to reduce the construction costs. As shown in Table I, all of these various widths of section apparently gave sufficient bottom velocities. The 20-ft. section was adopted as most advantageous for construction.

Aeration Tank Design—Consistent with rates established in experimental operation the present aeration plant is being constructed with an area of 2.5 acre and for an average capacity of 50 m.g.d., equivalent to 20 m.g.d. per acre. The diffuser area is 7.5 per cent of the tank area, but provision is made to increase this area to 10 per cent or more if found desirable or necessary. The plant is divided into seven units, five of which are full size and two half size. The first half tank is placed in a position and connected so that it may be used for re-aerating or re-tempering sludge. All tanks are 238 ft. long, 15 ft. deep and have a channel width of 20 ft. The full size units have four complete passes, which give a total longitudinal travel of the sewage of about 950 ft. With the baffling shown and the use of 1 cu.ft. of air per gallon, the surface

and bottom velocity of the tank will approximate 2 ft. per second and when operating at the rate of 20 m.g.d. per acre this will be equivalent to a spiral travel of more than six miles within the length of the tank.

The principal saving in construction of the type of aerator adopted over the usual type (with diffusers distributed over the entire bottom) is the lesser number of diffuser plates required and the elimination of a very expensive diffuser and floor system. The advantage of air circulation over such mechanical agitation as we have knowledge of is that with equal opportunity for economy due to the surface adsorption of oxygen there is an assurance of always having a sufficient quantity of entrained air to give positive oxidization throughout the sewage mass.

Construction Details—The diffuser plates in the aeration tanks are set in and above recesses cast in the floor and are inter-connected by 4-in. vitrified-glazed pipes imbedded in concrete in the 12-in. space between the individual plates. Fifty plates are operated from each air-control valve. The air is introduced in the middle of each section and by means of continuous circulation prevents the accumulation of water underneath any

struction are located in the influent and effluent channels. The maximum length of continuous wall in an east and west direction is 200 feet.

Operating Gallery—In the design and construction of the operating gallery, which includes the mixed liquor channel and the aeration effluent and sludge piping, special provision has been made for the distribution of mixed liquor without air agitation. This has been accomplished by careful proportioning of the channel sections and taking advantage of the short and direct connections between the aeration and settling tanks. The main air-supply line passes through this gallery and individual meters are provided with indicators and recorders for each tank. The aeration effluent is measured by Venturi meters placed in the connecting lines. Indicators and control devices are placed on the separate settling tank sludge lines in order to control the sludge returning to the system.

Activated-Sludge Settling Tanks—Considerable study has been given to the separation or settling of the suspended solids from the aeration effluent. It has been

All tanks operating on screened sewage.

section of the plate area. The recesses are formed in the concrete by the use of cast-iron cores joined together by structural-steel framework to insure alignment and uniformity in settling.

In the construction of baffle and dividing walls in and between the tanks an attempt has been made to take care of expansion and contraction entirely by use of temperature steel. These walls are designed as vertical cantilevers and are horizontally reinforced for temperature with percentages averaging 0.5 per cent of the sectional area and distributed from 1 per cent in the thin sections at the top to 0.25 per cent in the heavy sections at the bottom. Copper expansion joints of special con-

ADMINISTRATION BUILDING WITH OFFICES BELOW AND LABORATORIES ON SECOND FLOOR

realized from the work done that this problem is only indirectly related to the settling of raw sludge and the type of equipment which will operate satisfactorily on one may not produce good results in the other. We are convinced from our experience that activated-sludge settling tanks should be relatively deep and that the sludge should be removed promptly and without agitation. The influent should enter at either end and near the top and the settling cones be located as close as possible to the influent openings. This arrangement permits vertical settling and allows the coarse and heavier particles in falling through the partially settled sewage to carry down the fine solids and colloidal matter which may have a tendency to rise or remain in suspension. The clarified effluent should be drawn from near the middle and at the surface with sufficient weirage provided to take advantage of surface tension.

The Indianapolis plant has been designed with liberal settling capacities. Two settling tanks are provided for each full size aeration unit. Each tank is 78 ft. long, 42 ft. wide, oblong in plan, and has an area of about 3,020 sq.ft. Two settling cones are provided for each tank, with slopes one vertical to three horizontal. The final effluent is withdrawn from the tanks by three surface skimming troughs, each provided with two adjustable weirs giving a total length of 250 ft. for each tank.

Under normal or average operating conditions, each settling unit will receive sewage at the rate of 4.16 m.g.d. plus the returned sludge. On this basis they will

PLAN AND SECTIONS OF ACTIVATED-SLUDGE PLANT FOR CITY OF INDIANAPOLIS

operate at 1,350 gal. per day per square foot of area or, including 20 per cent returned sludge, 1,650 gal. per day per square foot. With an assumed maximum demand of 50 per cent this rate will be increased to 2,340 gal. per square foot of area. The settling period under average conditions and including 20 per cent returned sludge will approximate 97 minutes and for the extreme maximum condition 53 minutes.

The sludge removal mechanism consists of two revolving elements for each tank (two units being driven from a single motor). Sweeping chains are provided to keep the sludge from adhering to the bottom. By producing a slow rolling movement of the sludge these

chains assist in concentration in the cones. Each double tank is equipped with one 2-hp. electric motor which is direct-connected to the revolving element through spur-reduction and worm gear drives. The rate of rotation of the elements is one revolution each 19 minutes.

Main Power Plant—Electric power and air for the plant operation are furnished from the main power building located adjacent to the activated-sludge plant. In this building provision is made for eight 400-hp. water-tube boilers, four steam-turbine blowers and three steam-turbine generators and necessary auxiliary equipment. At the present time three boilers, three blowers with a capacity of 18,000 to 24,000 cu. ft. per minute and

two 500-kw. electric generators are being installed. The boilers will furnish steam at a working pressure of 225 lb. per square inch with a superheat of 100 deg. F. The guaranteed economy of the turbine blowers is 7.67 lb. of steam per 1,000 cu. ft. of air at 7.5 lb. gage pressure and of the electric turbines, 15.3 lb. of steam per kilowatt-hour delivered at the switchboard. An important

of sludge but with the character of sludge produced at Indianapolis, the problem is believed to be largely biological. From the records obtained from dehydration of sludge at other laboratories and demonstration plants, it is apparent that the Indianapolis sludge is of superior quality. This, together with the low cost of fuel and the absence of objectionable

ENLARGED CROSS-SECTION OF ACTIVATION TANK: DETAILS OF PIPING, FILTROS PLATES, BAFFLE WALLS

part of this plant is the air-washing equipment for the air supply to the blowers. It is guaranteed by a double system of washing to remove at least 99 per cent of all dust and floating particles contained in the air before washing.

Air Piping—The connecting air main between the power plant and the aeration units is 42 in. in diameter and contains the master air meter for integrating and recording the total quantity of air furnished. All air lines are cast-iron hub-and-spigot pipes in which provision is made at various points for expansion and contraction. These pipes are all heavily coated with a high-grade pipe varnish to prevent the air coming in

odors, was one of the determining factors in deciding on the activated system of sewage treatment.

Throughout the work at the demonstration plant many tests and experiments were made on sludge filtering. Both plate presses and continuous filters were used for this purpose. Either of these types gave reasonably good results when the sludge was properly conditioned, but did not produce a dense or satisfactory cake when the sludge was under aerated or otherwise out of condition. During the summer of 1922 sludge was dried on sand beds. In favorable weather a cake 1.25 in. thick containing an average of 88 per cent moisture was removed from the beds each 24 hours.

Dehydration Plant—On account of the uncertainty of this operation and the lack of experience on full size units, it has been considered advisable to construct the building for the dehydration plant, but without complete filter equipment. Dryers are to be installed for the concentrate thickener sludge and for activated sludge removed from sand beds which are intended to be used temporarily or until final dehydration methods are determined. This building will be 100x120 ft. in plan and will include two indirect rotary dryers 88 in. in diameter by 60 ft. long, equipped with induction fans, chain grate stokers, vapor condensers and dust collectors. Provision is made in this building for an additional drying unit and floor space 42x120 ft. for sludge filters or other means of dehydration. At present two full size continuous filter units have been purchased. One of these is a vacuum filter, the other of gravity type. It is intended that these units will be placed in service and the dehydration system fully developed under actual working conditions of the plant.

*The low production of the last two runs is accounted for by thin sludge due to insufficient settling capacity during this period.

contact with the iron. No steel is used in any of the air lines.

Sludge Dehydration—It is agreed that dehydration of activated sludge is a troublesome problem. Much research work has been done but as yet no universal method has been developed or adopted. Hydrogen-ion control seems to offer encouragement with some classes

Some Notes on a Brazilian Hydro-Electric Plant

Special Correspondence

ELECTRIC energy for the use of the city and State of Rio Janeiro and the federal district of Brazil is generated in a high-head hydro-electric plant about 45 miles from the city. An account of a recent trip to the plant arranged by the Club de Engenharia may give some idea to the readers of *Engineering News-Record* of the development in water power in this part of South America.

The railway transportation for the 45-mile trip over the Central of Brazil Railway was arranged by the club, with Fred Huntress, vice-president in charge of the Rio Janeiro Tramway Light & Power Co., as chief host for the visitors. From Lages station on the railway (gauge 1.68 meters) the trip to the power house was made by a special car and locomotive of the company. The distance is about 13 miles, and the line is generally through very low land that was a hot bed of sickness, malaria and other fevers when the company began construction. Men sickened and died so quickly on the other railway construction near by that it was almost impossible for the company to employ men when their railway construction began. Steps were taken as rapidly as possible to kill mosquitoes near the company works but it was very difficult to secure co-operation from the land-owners near by. It therefore became necessary to purchase an enormous tract of land and put a mosquito expert in charge. At the present time fevers and mosquitoes are practically unknown anywhere near the company works.

The party left Rio de Janeiro at 7:30 a.m. and reached the power house at 10 a.m. where inspection was made of plant and equipment.

Hydro-Electric Plant—The electrical equipment is principally Westinghouse. There are some Escher Weiss hydraulic equipment and Pelton wheels. The working head is of course variable with the season but at present it is about 304 meters. One of the wheels was idle for a short time and it was very interesting to note the conditions of the buckets. In many instances they had been very badly worn out but had been built up by electrical welding and later ground smooth with abrasive wheels. The phosphorus bronze nozzle center showed signs of considerable wear, both as uniform channels and as a succession of small ovals which would ultimately form channels. There are now eight wheels and the load in Rio de Janeiro averages about 900,000 kw.-hr. per day. At times it is over 1,000,000 among the 80,000 light and 4,000 power customers. An outdoor substation supplies the State of Rio de Janeiro, in which the plant is located, and there is a small interior department of the power house distributed to the works, the near-by farms and towns.

Water is wasted through the nozzles at times and strikes a small hill across the river where some very neat cylindrical tunnels have been driven into the rock with water at about 400-lb. pressure. It is in no sense a novelty to those who have similar barriers but is one of the things which always interests the visitors.

The power house employees have very fine quarters near the plant, entirely screened as at Panama with beautiful gardens round about.

To reach the upper plateau from the power house, a 66 per cent cable incline over a stone-paved roadbed is used. The faces of the cuts are painted with a gas house tar to protect the earth against vegetation, rain and the burning sun. It has given general satisfaction and is a well established custom in various parts of Brazil.

From the top of the incline to the general office and home of the director of the works the distance is about three kilometers by a very good earth road. This is the ideal country home with a farm and excellent orchard alongside, telephone connection to nearly every city, town or farm within 200 miles, radio receiving set for the opera in Rio and the best papers and magazines from a half dozen countries.

Fast teams of round little mules took us to the dam which is on a radius of 100 meters and 45.50 meters high. It was built under the direct supervision of C. H. Kearny of San Antonio, Texas, and stores 210 million cubic meters. The lake is very surprising as it follows a narrow canyon for nearly 20 miles and runs back into many tributary gulches. One can throw a stone across in many places. The company's power boats travel along rapidly and one can see most of it in a short time.

The property is exceedingly well managed and throughout the organization an esprit de corps exists which many managers might well envy.

Relation of Railway Wheels and Rails

THAT THE TAPER of wheel treads is a very small factor in the relation of rail heads to wheel treads is shown in the report presented by the committee on Wheels at the recent Chicago convention of the mechanical division of the American Railway Association. The note in question, abstracted below, relates to a joint meeting of this committee with the American Railway Engineering Association's committee on Track Stresses.

In a full discussion of tread design of wheels and its relation to the canting of rails, it developed that there is little information as to small or large taper of wheels in its effect on the rail. It was brought out that the spreading of rails and the wearing into tie-plates and ties on the outside is a serious problem and that many railroads are meeting this by canting the rails. Some of the engineers have felt that the wheel tread should have a lighter taper than 1 in 20 in order to help relieve this condition. But wheels and rails both wear quickly after being put into service and any relation between the tread contour and the contour of the rail is soon lost. Thus it would not appear likely that a slight alteration in the taper of the wheel would remove this condition. Furthermore, the main cause of the spreading of the rail is entirely independent of the tread taper.

The committee of the engineering association asked as to the possibility of any change in the taper of the wheel, in order that it might have a permanent basis for a recommendation for canting the rails. The committee on Wheels stated in reply that it has received no data which would warrant making a change in the taper of the wheel tread. The present taper is thought to be most advantageous, as regards flange wear. The last change made was in 1907, when the taper was changed to 1 in 20 from 1 in 25. At the present time, practically all wheels (except those for a few roads) are being made with this standard taper. The committee advised the A. R. E. A. committee that it had under consideration the making of the tread with a single taper of 1 in 20 instead of the present double taper, and this procedure met with the approval of the latter committee.

Geology and the Decatur Dam and Reservoir Project

Glacial Formation Explains Why Sheet Piling Could Not Be Driven to Intended Depths—Watertightness Assured

By MORRIS M. LEIGHTON

With Illinois Geological Survey, Urbana, Ill.

EXPERIENCE has taught the engineer that the construction of a dam across any valley in the glaciated area must be undertaken with unusual caution. The materials beneath the dam must have sufficient bearing power to support the weight of the dam, and must be tight enough to prevent seepage from beneath. The materials at the ends of the dam and in the natural walls of the reservoir must also be such as to prevent excessive leakage. In order to pass judg-

FIG. 1—THE GLACIAL GEOLOGY OF THE DECATUR AREA

ment upon the character of glacial formations at a given locality, having in view a reservoir project, the engineer desires to know the kinds and thickness of materials present, their texture and compactness, the relationships of the porous to the non-porous and their relations to the bedrock. Obviously a full knowledge of these things involves an understanding of the principles of glacial and aqueo-glacial sedimentation and in some cases the differentiation of drift-sheets.

At Decatur, Ill., a new dam has been constructed across the Sangamon River, which flows through the city, thereby creating a reservoir in the upstream portion of the valley for a distance of 12 miles and covering 3,900 acres of territory. The specifications called for a dam 15 ft. high above the old river level; and for the base of the dam to be 72 ft. wide, which is inclusive of a concrete apron but exclusive of a 30-ft. clay apron on the upstream side. The base was to extend to a

depth of 3½ ft. below the lowest part of the river bed, below which cutoff sheeting was to be driven to a maximum depth of 30 ft. below the base of the concrete portion of the dam. The middle section of the dam was to be of concrete, but the end sections of earth, with the cutoff sheeting reaching to somewhat less depth than in the middle section. The supervision of construction was entrusted to the firm of Pearce, Greeley & Hansen, consulting engineers, of Chicago, who assigned J. Albert Holmes to the position of resident engineer.

Before formulating the specifications, a preliminary series of test-holes was made across the valley to ascertain the character and thicknesses of materials. Samples were collected, but due to the fact that these were from a churn drill nothing but sand and gravel was reported. Upon these data the specifications were drawn and the work was undertaken. Later in driving the cutoff sheeting, a "hardpan" at varying depth was encountered which was impossible to penetrate and which prevented the driving of the sheeting to the depths specified.

The question then arose as to what this "hardpan" might be—is it solid bedrock, or cemented gravel, which might be porous enough to permit excess leakage, or some other kind of material which might or might not menace the success of the dam construction or the reservoir project. Obviously it was necessary to have these questions answered, and a geological examination was accordingly requested.

Geological Phenomena—Decatur is situated on the eastern border of the Shelbyville Moraine (see Fig. 1), which here has a width of several miles. No bedrock is exposed in this vicinity. The altitude of the moraine at the river bluff is reported to be about 650 ft. above sea level. The valley at Decatur is about 50 ft. deep, but farther west in the moraine it is 75 ft. or more. West of the moraine it is scarcely over 50 ft. but is much wider than in the moraine. This seems to indicate that the portion beyond the moraine is pre-Wisconsin in age, quite in harmony with the fact that some of the tributaries are beheaded by the Wisconsin deposits. The incision of this part of the valley in Illinoian drift would therefore make its age post-Illinoian and pre-Wisconsin.

Frank Leverett ("Illinois Glacial Lobe": U. S. Geol. Surv. Mono. 38, p. 518, 1899) states that the average thickness of the Shelbyville drift is 100 ft., an estimate based on the relief of the moraine. If this were the case, it would seem that the valley through the moraine must have been completely filled, but this figure seems excessive, and there are reasons for believing that the valley was not buried.

After the hardpan was discovered a new series of

TABLE 1—GENERALIZED SECTION OF THE STRATA IN THE SANGAMON RIVER VALLEY NEAR DECATUR, AS DETERMINED FROM BORINGS AND TEST PITS

	Description of Strata	Thickness, Ft.
3.	Soil and flood-plain alluvium, a brownish sandy silt toward the valley walls, becoming darker near the stream	5-10
2.	Sand and gravel, distinctly sandy, thin out toward the valley walls, thickens toward the stream, maximum thickness	
1.	Till, called "hardpan" by the drillers, dense, compact clay with scattered pebbles and boulders, difficult to penetrate; contains a few thin layers of sand, most of them limited in thickness from 1 to 2 ft., but one on the south side having a maximum thickness of 18 ft. Maximum thickness of till penetrated	35
		54

well borings was made—this time in such a way that cores of the material, as it actually occurs, were taken at desired intervals. Credit for the admirable way in which this series of borings was made belongs to Mr. Holmes. Twenty borings were put down across the valley in line with the proposed dam. These revealed the strata, as shown in Fig. 2.

A short distance farther west, in the moraine, a new sewage ditch had exposed some excellent sections of drift for study. Here the till contained thick lenses and considerable bodies of gravel and sand, some of which show marked contortion by the overriding ice. One of these lenses was about 200 yd. long. If such a lens were to occur in the till beneath the dam, it might permit excess leakage. But the till beneath the dam appears in the main not to belong to the Shelbyville terminal moraine, like that shown in the sewage ditch, but to belong to the Illinoian ground moraine. If so,

FIG. 2.—CROSS-SECTION OF THE SANGAMON RIVER VALLEY AT DECATUR

then by virtue of its mode of origin chiefly beneath the ice, it would likely contain but little gravel. Instead, its constitution would be chiefly till, possessing a clayey matrix nearly impervious to water. The evidences that the till beneath the dam is chiefly Illinoian in age will now be considered.

Superposed Drift-Sheets in the North Valley Wall—In the north valley wall at the dam site, the construction company opened a clay pit for securing clay filling. An unusual section was exposed, showing the following sequence:

3. Till (probably Wisconsin) overlain by "wash" from the slopes and capped with soil; upper part, including "wash," is leached 3 to 4 ft., the underlying 0 to 2 ft. being calcareous; total exposed, 4½–7 ft.
2. Old soil (probably Illinoian), gray below the soil, brownish below, leached 3 to 4 ft., calcareous below, compact; total exposed, 6–8 in.
1. Till (probably Illinoian), gray below the soil, brownish below, leached 3 to 4 ft., calcareous below, compact; total exposed, 6 ft.

Quite clearly, this section shows two distinct till sheets, separated by an old soil and the lower till exhibiting decisive evidence of leaching and oxidation before the deposition of the overlying till. The upper till doubtless belongs to the Shelbyville terminal moraine of Early Wisconsin age, the lower to the Illinoian drift-sheet.

A short distance west, there was a ditch excavated for the cutoff sheeting, which transects the valley slope. Upon examination this was found to show the same sequence of materials. Here, fortunately, the trend of the exposure is at right angles to the valley and shows the relation of the pre-Wisconsin surface to the valley. The contact between the two tills dips steeply toward the valley in conformity with the present north valley wall, strongly suggesting at least two things: (1) That the north side of the old Sangamon valley at this

place was not completely filled by the Shelbyville ice deposits, and (2) that of the amount which was deposited on the north side, little remains from the erosion of the present stream. By projecting the contact into the valley, its position would be such as to make most of the till beneath the gravel filling referable to the Illinoian deposit. Hence, it appears that the sand and gravel filling rests almost directly on Illinoian drift with but little Wisconsin drift intervening. Further evidence was found by a study of the excellent series of core samples from the later series of borings. Some of those from the middle portion of the present valley showed brown till, partly below blue till and partly directly below the sand and gravel filling.

The South Side of the Valley—The south side of the valley was filled with greater quantities of drift, which accounts for the present valley being narrower than one would expect, judging from the width of the valley

beyond the moraine. No exposure of an old till or no evidence of the old valley wall was found on the south side. All of the material, save for a thin mantle of loess, appears to belong to the Shelbyville drift. As will be seen in Fig. 2, there is a body of sand and gravel, revealed by four borings, separating the blue Shelbyville till above from the brown Illinoian till below. This is interrupted as a part of the outwash of the advancing Shelbyville ice, which later was overridden and buried by the deposits of blue till.

The sand and gravel filling in the Sangamon Valley has already been noted. No distinct terrace is shown at the dam site, but on the south side of the valley slightly above the present flood plain, gravel underlies alluvium and "wash" from the south slope. All of this gravel filling is believed to be correlative with the remnants of gravel terraces which occur both upstream and down, and which appear to have been deposited as a valley train from the ice during its recession from the Shelbyville moraine and during the building of the next younger Cerro Gordo moraine. (Fig. 1.)

Summary of the Sangamon Valley History at Decatur—The valley dates back to the Sangamon interglacial epoch, probably even to the close of the Illinoian glacial epoch. Upon the melting of the Illinoian ice, the area was a flattish ground moraine, and the Sangamon River was formed by the consequent drainage. During the Sangamon interglacial epoch a relatively broad, shallow valley was carved at Decatur commensurate with that portion of the valley beyond the Shelbyville moraine. Contemporaneous with the valley cutting, the Illinoian till above river level was leached and oxidized and soil was developed, extending down some parts of the valley

slope. To some extent beneath the old flood-plain the till was oxidized to a brownish color but scarcely leached.

The change of climate from warm to cold and the accumulation of a great thickness of ice over eastern Canada resulted in the Wisconsin ice invasion, which reached its extreme limit a few miles west of Decatur. During the ice advance glacial waters deposited the body of sand and gravel which lies between the two tills on the south side of the valley. Later this was overridden and for a time the ice edge remained within the zone now occupied by the Shelbyville moraine and radically changed the contour of the Illinoian surface by depositing a notable moraine. Some of the debris was released directly from the ice upon its melting and deposited as unassorted drift or till, while some was deposited by glacial waters, forming gravel bodies. Readvances of the ice contorted the gravels and buried them with till. As a result, the moraine was formed of both till and bodies of sand and gravel with complex unpredictable relations.

The amount of drift deposited across the valley was not enough to fill and eradicate the valley. A depression was left to serve as a drainage line upon the retreat of the ice front. In this inherited depression, after some modification by the glacial waters, a valley train was deposited, which came from the ice during its melting back from the Shelbyville moraine and during the building of the Cerro Gordo moraine. Since the disappearance of the ice, the sand and gravel fill has been partly eroded away and a flood plain of varying width has been developed on both sides of the stream.

Relation to the Reservoir Project—According to the foregoing interpretation, the hardpan, or glacial till, on the north side of the valley, which is to receive the cutoff sheeting, is drift of the Illinoian ground moraine and not drift of the Wisconsin terminal moraine. Since the drift belongs to the ground moraine phase, it was deposited chiefly beneath the ice and consequently has a maximum content of impervious clay matrix and a minimum of sand and gravel layers which might serve as avenues of sub-surface leakage. On the south side of the valley, the cutoff sheeting ends in the Wisconsin drift. The gravel body, 6 to 13 ft. in thickness, which separates the Wisconsin and Illinoian tills, is apparently the only one which menaces to any degree the success of the dam. Due precaution was taken by the resident engineer, who, realizing the possibility of some excess leakage at this place, made provision for such an emergency.

Vancouver Dock Work Revived

The Vancouver drydock project, which was suspended for several months, has been revived and the Wallace Drydock Co. has been awarded the contract. The drydock will be of the floating type, to cost \$2,500,000, and will be built on the north shore of Burrard Inlet, opposite Vancouver. The construction program is subsidized by the federal government. The plans call for a 15,500-ton drydock, 500 ft. long by 132 ft. wide, in two sections, each containing five pontoons 44 ft. long, constructed of heavy timbers; a third section will give a total length of 700 ft. A 700-ft. pier, 50 ft. wide and placed on concrete cylinders, is to be built alongside the drydock. Steel machine shops, to be erected, will house a 30-ton traveling crane, and the pier will have a 7-ton traveling crane.

An Optical-Lever Extensometer of Wide Utility

Abstract of a paper by L. B. Tuckerman, Bureau of Standards, at the recent Annual Meeting of the American Society for Testing Materials.

A STRAIN-GAGE or extensometer of small size, high sensitiveness and convenient adaptability to various uses has been developed by Dr. L. B. Tuckerman, of the Bureau of Standards. It uses a Martens tilting mirror, but with a triple mirror in place of the single mirror of the Martens instrument, and couples with it a combined illuminator and reading telescope which eliminates the great

AUTOCOLLIMATOR

CONSTRUCTION OF AUTOCOLLIMATOR

SINGLE MIRROR SYSTEM

DOUBLE MIRROR SYSTEM

TRIPLE MIRROR SYSTEM

TRIPLE MIRROR WITH FLASH

FIG. 1—AUTOCOLLIMATOR AND TRIPLE MIRROR

degree of susceptibility to disturbance of the ordinary optical-lever system. In the instrument as constructed a single scale division represents 1/25,000-in. change of length, and tenths of a division may be read.

In Fig. 1 is shown at the top a diagram of the illuminator and reading telescope combined in a single unit called the

FIG. 2—BACK AND FRONT OF MIRROR PRISMS

autocollimator, a full drawing of which, somewhat diagrammatic, is given just below. This combination makes the reading system entirely self-contained, but the reading is still dependent on the mirror position.

With a single mirror, as shown in the left-hand sketch in the lower part of Fig. 1, the reflected light ray misses the reading telescope upon even a minute shift or tilt. This difficulty is obviated, in part, when a double mirror system is used, as shown just to the right; the telescope then is able to take a reading in any position at right angles to the line of intersection of the two mirrors. In order to make the arrangement also insensitive to disturbances in the other direction, a third mirror is introduced, as shown in the left of the lower line of diagrams in Fig. 1. This is the arrangement used in the Tuckerman instrument, except that for auxiliary purposes a fourth mirror is formed by grinding away the corner of the double mirror unit, as shown in the right.

Prisms are used instead of mirrors, because accurately plane surfaces are more easily obtained in them. Fig. 2 shows the actual prism system used in the Tuckerman

FIG. 3—TWO-INCH STRAIN-GAGE

strain-gage, comprising an ordinary 45-deg. prism as a single mirror (mirror 4 of the diagram), and a roof prism with its corner cut away.

The complete strain-gage is shown by drawing and photograph in Fig. 3. The knife-edge *A* is fixed, that at *E* is the tilting knife-edge carrying the mirror prism. The roof prism *D* is carried on a lever whose position may be adjusted by a double cam *E*, giving a coarse and a fine adjustment in order to bring the fiducial mark of the vernier to zero on the scale. The Martens lozenge *B* is 0.2 in. high, and with this construction one scale division represents 0.00004 in. deformation.

A photograph of the field of view obtained with the collimator is reproduced in Fig. 4. The image of the scale and the vernier reflected alongside it is seen in the center of the field; as will be seen, tenths of a division may be read. The bright patch at the top of the field is the "flash," which is an image of the collimator field reflected from the beveled corner of the roof prism. So long as this flash is in the field of view, the autocollimator is close enough to the true right-angle relation to the strain-gage mirrors to make the cosine error negligibly small.

Several of these small strain-gages have been constructed by the Naval Gun Factory, Washington, for tests on large riveted joints for the navy. It is planned to place thirty of the strain-gages at various points on the riveted joint, and read them by means of two autocollimators.

It is believed to be possible to apply this strain-gage to

FIG. 4—FIELD OF AUTOCOLLIMATOR, FLASH AT TOP

gage lengths even as small as $\frac{1}{4}$ in. for fuller exploration of deformations in strained members. The light weight of the gage also makes it applicable to many cases of strain measurements where heavier instruments cannot be used, as in the case of thin sheet metal or wire. The gage is now being adapted to a torsion dynamometer for rotating shafts at the Bureau of Standards, and still other applications are in contemplation.

Another Cross-Connection Typhoid Outbreak

Only seven months after the typhoid outbreak at Franklin, N. J., due to cross-connection between a municipal and an industrial water supply, states the New Jersey *Public Health News* for June, 1923, another typhoid outbreak has occurred that seems to be due to almost identical conditions. The record outbreak was in Rockaway. From the onset of the first case on May 25 up to June 25 there were 41 cases and 4 deaths. The record down to July 31, according to D. C. Bowen, chief of the Bureau of Local Health Administration, was 46 cases and 6 deaths. The cases are confined to the eastern end of the borough, beyond a point where there was a cross-connection with the fire mains of an industrial plant, separated from the potable supply by a single check valve. Examination showed that this valve was "stuck open and so encrusted with dirt and rust that the flap could be moved only by the use of a bar." Formerly the town pressure exceeded that in the industrial water-supply system. Examinations made under the direction of Mr. Bowen showed that the industrial water supply received the effluent from a septic tank located only some 200 ft. upstream from the pump intake. It was also found that at the time the infection occurred the excretions from a typhoid carrier of three years' standing were going into the septic tank. Action taken to control the outbreak included severance of the pipe forming the cross-connection, which was done on June 16, abundant use of bleaching powder in the privies of the borough, disinfection of the discharges of all typhoid patients, and free inoculation with anti-typhoid bacteria of all residents of the borough who would accept it, the latter being offered by the local board of health.

Recent Railway Location in Southern Colombia

Difficult Problem of Linking Up Cities in the Andes Mountains—Providing an Outlet to the Sea—Lack of Transportation Facilities—No Local Subsistence

BY F. R. MOLTHER

Former Office Engineer, D. E. Wright Construction and Engineering Co., Inc., Panama

ALTHOUGH the theory of railway location rarely comes up in present-day engineering practice in the United States, it has never diminished in importance nor been backward in development. It is believed, therefore, that the following article will be of some technical interest describing as it does some location problems presented by the difficult topography of the Andes, where as much as anywhere in the world the

South American continent, possesses great natural resources the development of which is limited, however, by the extreme lack of transportation facilities.

It is to be expected that plans for the betterment of such limiting conditions are both numerous and extensive. Because of a loosely jointed central government, unable to project its influence to the more distant and inaccessible states, plans for better transportation vary greatly and each of them is sponsored by those areas which would be best served by it. The decision as to the encouragement of some plan or another is a problem that confronts every administration at Bogota.

Recent Railway Projects—One of the earliest railway projects was that of connecting the capital, Bogota, a city of 150,000 people on the great Cundinamarca plateau 8,000 ft. above the sea, with the Pacific Coast at the port of Buenaventura. This work was commenced in 1877 by Francisco Cisneros, the most prominent railway engineer in the history of Colombia, and the road is now in operation as far as Buga. At the important city of Cali, in the heart of the extensive and fertile valley of the Cauca, a branch toward the south has been constructed to within 50 kilometers of Popayan, an active city of 15,000 inhabitants, capital of the department of Cauca, and a thriving center in a cattle and coffee producing region, with a climate suitable for raising potatoes and wheat. Recent consideration of the importance of better communication among the departments of the country has given rise to a study of the continuation of this branch to the frontier of Ecuador, by way of Popayan, Pasto, capital of the department of Nariño, and the important towns of Tuquerres and Ipiales in the same department.

Another, but wholly new proposal for railroads in the isolated department of Nariño, which is now without a single kilometer of railroad, is that of connecting the capital city of Pasto with the Pacific at the port of Tumaco.

The contract for the location of these two lines, from Pasto to Tumaco, and from Popayan to Ipiales, on the frontier, was let in September, 1920, to the Wright Engineering and Construction Co., Inc., of Panama, and the work was completed in August, 1922. The purpose of this article is to indicate the location problems and solutions applied on the surveys for these lines, without consideration of their particular importance, the discussion of that question requiring recognition of all the many routes proposed for better transport facilities in Colombia.

These surveys were made by three organizations operating independently each consisting of a chief of party, transitman, levelman and topographer. In very rough country, of which these routes were required to cover many kilometers, two topographers were employed, and the use of a field draftsman in one party seemed to justify this addition to the staff. Two Colombian engineers were employed in each party, as required by the contract, usually as topographers or

THE VALLEY OF THE GUAMBUYACO RIVER BETWEEN
PASTO AND POPAYAN

country calls for a good understanding of railroad requirements. In addition to this, the fact that American engineers and American capital are continually finding Latin-America a broader field for their development may also add to the interest in the discussion.

Transport Situation in Colombia—The Republic of Colombia, situated at the northern extremity of the

levelmen, and despite the limitations of rudimentary training and inexperience they generally gave satisfaction. Several Panamanian negroes were brought down to serve as chainmen and rodmen, but proved to be of greater value in the kitchen, and finished the work as cooks. Native peons were developed into competent chainmen and rodmen.

Because of the isolation of these commissions while in camp, away from towns and traveled roads, it was necessary for each camp to be self-sufficient, and to carry all of the supplies needed for any contingency, in addition to the technical equipment.

All supplies that could be so accommodated were packed in wooden boxes 31 x 17 x 12 in. deep, experience having determined that these were of the most convenient size and weight for the little Colombian pack animals to carry in pairs. Each man on the staff was allowed one such box of personal equipment, without shoes, which alone constituted half a cargo, for no amount of hobnails could prevent cutting the best boots and shoes to pieces on the rocks, or pulling out the seams on the steep slopes.

In territory infested with mosquitoes or gnats, each man had a mosquito bar of thin muslin, and not only was sleeping made quite comfortable, but most of the party also escaped malaria. The peons, however, who slept without mosquito bars, suffered greatly from fever, and many pounds of quinine were required to keep them in working condition.

The cook had horses and pack-animals for trips to market—held weekly in the small villages that were usually two days' trip from the camp—which afforded fresh meat, fruit and vegetables. Staple groceries were obtained monthly from the nearest large town, sometimes a journey of two weeks away. For several months the inaccessibility of markets, and the large force of peons employed, required butchering in the camp. Beef was usually killed at the end of the week, and pork or sheep at more frequent intervals. Chickens, sheep and pigs were carried by the camp party, and driven from camp to camp if not consumed at once. For several months game solved the question of fresh meat, one peon serving as hunter. Often deer or antelope were brought in three or four times a week. Wild turkey and ducks also were available for food.

Camps were built at intervals of about every 15 km. as it appeared undesirable to have the field parties cover a greater distance in so precipitous a country, with no paths other than cattle or antelope trails. Occasionally the topography recommended the use of temporary "fly" camps in which the party sometimes stopped for a night or two to avoid a particularly dangerous journey through canyons and over precipices to the main camp. Camps were built of wild cane, using the stalks to form the walls and one end of a rectangular structure having a ridge roof thatched with cane leaves. This resisted the rain in the arid country through which much of the survey was run. As the rainy season advanced, however, it was occasionally necessary to reinforce the roof with a tent fly lashed over the thatch. Beside such a house for the staff, a shelter was also constructed for the cook and his helpers, and two for the peons, or laborers.

All moves from camp to camp were made by pack-trains, which by reason of inadequate roads often were unloaded to pass the cargoes around some narrow section of trail, which a loaded animal could not pass.

Although the topography of the route was very broken, and several times the line ran close to those traditionally inaccessible sites selected by eagles and condors for their nests, the familiar method of reading angles with a transit and chaining the distances was employed in location. Levels were taken with a wye-level at every 20-m. station, except when steep canyons justified the location of an elevation on the far side with the instrument, and the use of a Locke level to fill in the descent and the rise. From these elevations the topography was taken in a 200-m. belt, half on each side of the line, the even contours being picked up with the Locke level, and located by pacing or measuring with the rod. For a stretch of seven kilometers in the Guambuyaco Canyon, the route of the projection was impossible for the instrument and chain. Here the survey line was run at the bottom of the canyon, on

MOVING THE DRAFTING OFFICE

such banks as the stream offered, but often in the river itself. Topography was taken by stadia, employing the vertical and horizontal angles, and the mapping was done by interpolation between these miscellaneous elevations at the tops of banks and noses of ridges, to arrive at the even contours.

In order to accommodate as much of the line as possible on comparatively narrow sheets, the latitude and departure of each course were determined from a chart, and all critical hubs, at points where the general direction of the survey changed greatly, were computed and plotted at 1:10,000 scale. Selecting a meridian for each sheet, the hub for starting was located in the most advantageous position for accommodating as much line as possible, and the hubs were plotted at 1:2,000 for the detail study. The courses were run off by determining their angle with the meridian of the sheet, and by drawing in their direction, with respect to this meridian, by the method of tangents and co-tangents (*Engineering News-Record*, Dec. 14, 1922, p. 1032). The topography was then spotted on at each station where sections had been read and the contours were sketched on from the field book, which contained the contours drawn in between the sections where elevations were read. This permitted the covering of all small breaks in the ground, without location contours oftener than every hundred meters, in normal country with regular slopes. Some stretches, however, of badly complicated topography required locating the contours at every 20-m. station. When the slopes permitted, contours were drawn at 2-m. intervals, but much of the line permitted the showing of 10-m. contours only, at the scale employed.

The survey line was inked in red before the topography went on, and all contours and streams were inked before location was begun. The projection was made according to the method described in the late A. M. Wellington's classic work on the "Economic Theory and Practice of Railroad Location." This method consists of drawing in the grade contour, for the grade as predetermined or suggested by the country, and approximately run by the transit line, and of fitting this grade contour as nearly as possible within the limitations of acceptable alignment.

A profile was then taken off on Plate A paper, at scale of $\frac{1}{2}$ in. to 20 m. horizontally, and $\frac{1}{2}$ in. to 2 m. vertically. Decision was then reached as to the means of crossing all openings, and estimates of all material were made.

A general map at a scale of 1:500,000 was made to show the general routes, from which the map accompanying this article was sketched.

Pasto-Tumaco Location—Little previous work had ever been done in this section of Colombia, no railroad route from Pasto to Tumaco had ever been considered, and available maps and information were unreliable.

The general features of the location required reaching by one of the several river routes from Pasto the plateau of Tuquerres, which lies to the south of Pasto and extends roughly from the Sapuyes river to that bend in the Andean Cordillera which includes the peaks of Cumbal, Chiles, and Troya. Accordingly, leaving the point selected in the outskirts of Pasto, for yards and terminal, at an elevation of 2,590 meters, the location proceeds 17 kilometers upstream in the valley of the river Pasto, and employing the slopes of the western cordillera, reaches the pass known as the Cruz de Amarillo, at an elevation of 3,172 meters. This pass affords access to the watershed of the river Bobo, which is followed down to its junction with the river Guaitara, where the line crosses the latter stream at an elevation of 1,797 meters, 300 meters above the level of the water, which is here sharply enclosed in a vertical box canyon. The crossing selected is the same as that chosen by Doctor Uribe for the Pasto highway. It requires the only steel bridge in this location with but 36 m. of span, and also affords a passage for the highway. The Guaitara bridge is 50 km. from Pasto by the railroad location, and grades up to $4\frac{1}{2}$ per cent compensated are employed to this point. The Guaitara canyon is followed upstream to the mouth of the Sapuyes river, and the valley of that stream and of the small creek, Los Molinos, takes the location to the important town of Tuquerres, 82.5 km. from Pasto, at an elevation of 3,040 m.

From this point the country dictated crossing the Tuquerres plateau, rising at its edge to the best pass between the Sapuyes drainage and the watershed of those rivers flowing directly westward to the Pacific. For this purpose the pass of Chimingual, 106.5 km. from Pasto, was selected. This lies at an elevation of 3,226 meters, the highest point touched by any of the surveys on this work, and is reached by 4 per cent compensated grades.

From this point, the only remaining problem was to reach the coast by the most favorable and direct route and as the pass of Chimingual suggests the use of the valley of the Guabo river, a precipitous descent of 1,200 meters is made at Chambú, the most favorable

place for the necessary development, 27 km. in length but so spiralling as to cover but 11 km. in horizontal distance. At one point near the top of this development the line appears below seven times in a horizontal distance of 3.5 km. and a vertical drop of 627 m. The length of this part of the spiral is 16 km. and here are required the only tunnels on the route, one 170 m. long and one 360 m. long. Once in the valley of the Guabo River—also known as the Calera, and farther downstream as the Guiza—the route continues downstream to a point where the river boxes up in a vertical canyon, and the line climbs out to the valley of the Güelmambi. The grades from Chimingual to this point do not exceed $4\frac{1}{2}$ per cent compensated. Soon catching the divide between the Mira and Rosario rivers, the location proceeds by its crest to avoid crossing the tributary small streams on each side of the ridge. The fact that the topography here is that of the Pacific coastal plain makes the use of this ridge acceptable, and preferable to the bottom of the valleys. This divide is followed as far as a point opposite Tumaco called El Pindo, where the crossing of a narrow estuary gives access to the island on which that city is located, 313 km. from Pasto, and 4 m. above sea level. The last 130 km. of this line are all below the elevation of 1,000 m., and no grade is greater than 3 per cent compensated.

No grade on this location was permitted to exceed $4\frac{1}{2}$ per cent compensated. This was one of the predetermined limitations of the contract, as was also the alignment limitation to curves of not less than 16 deg. metric, equivalent to about 6 deg. 6 min. English, which gives a radius of 71.85 m. The minimum of tangent between curves of opposite flexure was 40 m.

Pasto-Popayan Location—The situation north of Pasto had been scarcely more explored than that to the south, although a survey was made in 1893 by the late Colonel Shunk for the Pan-American Railway Corp., over the entire Andean range, including the cities of Pasto and Popayan. Urged, no doubt, by excellent reasons, Colonel Shunk located most of this line on the slopes of the central cordillera, which, for our purposes it seemed undesirable to follow, so the splendid data collected by that organization were unavailable for our use. From a point in the valley of the Patia River, Colonel Shunk's line somewhat follows this new location, which will be discussed later.

To reach the frontier, the Pasto-Popayan line employs that portion of the location previously discussed, from Pasto to Tuquerres, and a further branch of 34 km. southward on the Tuquerres plateau that is without technical difficulty.

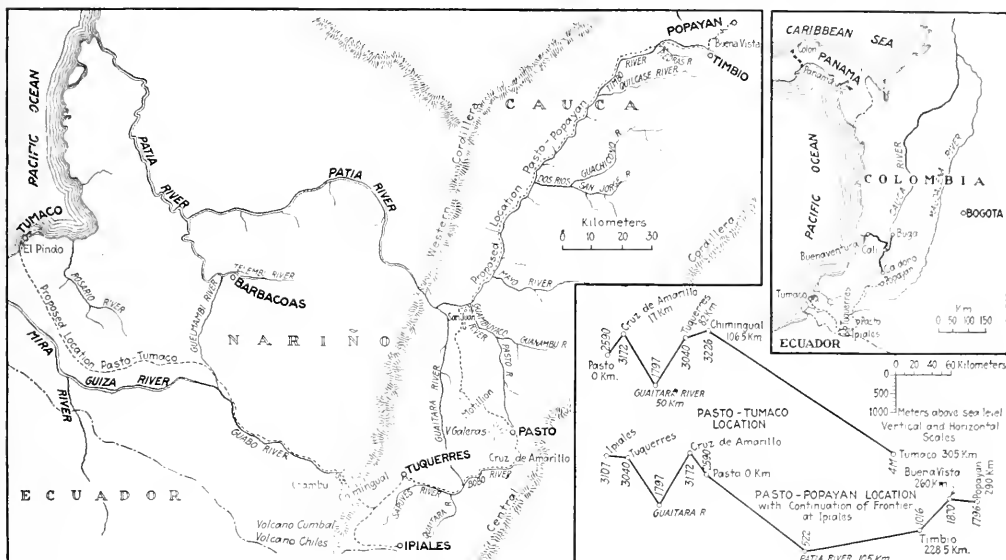

North from Pasto the first problem of the location was to reach the long basin of the Patia River, reconnaissance showing this route to be much less expensive and only slightly longer than the location in the slopes of the cordillera, made by Colonel Shunk. For the purpose of reaching the Patia River, however, this project was not so fortunate as the other, the only available basin, that of the Pasto River, turning out on reconnaissance to be disappointingly full of vertical canyons. The line leaves Pasto from the same point chosen on the Tumaco survey for yards and terminal, and follows the valley of the Pasto until its precipitous banks require the use of the slopes of the divide between the Pasto and Guaitara valleys. By these it attains the pass

of Motillon, whence the projection follows the right slope of a spur from the central cordillera to the pass of San Juan. There the route takes the left bank of the Patia River to the junction of the Guambuyaco River with the Patia. At this point the distance of 91 km. from Pasto proved to have been insufficient, at the rate of grade imposed, the line being at an elevation of 740 m., and the river more than 200 m. below. For this reason the line was run up the Guambuyaco canyon for a distance of 7 km. to catch the level of that stream, at 596 m. above sea level, and returns by the northern bank to the Patia River.

Here the second portion of this location is encountered, that of following the Patia valley as far as its grade might permit, the direction of that stream being conveniently northward with a slight eastward com-

per cent compensated for 40 km. upstream from the mouth, the river grade between these flatter stretches stiffens to 10 per cent. It was necessary therefore, to cross the Timbio at an elevation of 1,016 m., 228.5 km. from Pasto, and to employ the valley of the river Piedras, on the other side, for development, this being the only stream within reach that was not too steep.

At this point the next characteristic of this location became evident, that of leaving the friendly valleys of the Patia, Timbio and Piedras that had carried the line most satisfactorily for 150 km., to cross the continental divide to Popayan. Running up the Piedras for 4.5 km. and crossing at 1,120 m. above sea level, to continue rising on the northern side, with the maximum grade, found the line sufficiently high to ride out of the Timbio valley, cross that river again near the town of Timbio,

MAP OF SOUTHERN COLOMBIA SHOWING THE LOCATION OF PROPOSED RAILWAYS

ponent. The right bank was chosen, to avoid the wide crossings of the rivers Mayo, San Jorge, Guachicono and Quilcase and for the advantage of better topography in other respects.

The crossing of the Patia was effected at Km. 105 from Pasto, at an elevation of 522 m. above sea level, the lowest point in both these projects, except for the termination of the Tumaco line at the coast. The valley of the Patia afforded an excellent route as far as the junction of the Quilcase and Timbio rivers, which form the Patia at that point. Here Colonel Shunk, who had maintained his location far to the east and above us, on the other side of the Patia, dropped to the banks of the stream, and rejecting the Quilcase valley, as we did, because of its more circuitous route and deep upper valley, assumed that the Timbio would carry his grades throughout. He took up his survey on the upper banks of the river above the town of Timbio, on the slopes of the central cordillera again. This assumption, however, is not justified, for although the upper valley of the Timbio near the town of the same name, is flat, and the lower portion carried our limiting grade of 3.5

and cross the continental divide at the pass of Buena Vista, with an elevation of 1,870 m., the highest point on this location since leaving the corresponding elevation in the first descent from Pasto.

From this pass the final requirement of this location was solved by running toward the city of Popayan in the most direct route, crossing three small rivers near their sources at right angles, to arrive at Popayan, 290 km. from Pasto, and 1,796 m. above sea level.

The entire 290 km. from Pasto was located with no greater grade than 3.5 per cent compensated, the contract requiring this limitation as well as that of 16 deg. metric curves for a minimum. These are equivalent to about 6 deg. .06 min. English, and have a radius of 71.85 m. The minimum tangent between curves of opposite flexure was 40 m., and the rugged nature of the topography traversed is demonstrated by the fact that the line was 49.3 per cent curve, employing 69,000 degrees of central angle, and leaving 147 km. of tangent. The line had 50 km. of level grade, 130 km. of plus grade toward Popayan, to rise 1,900 m., and 110 km. of negative grade, to fall 2,700 m.

Fire Destroys Old Wooden Bridge

BY CHARLES A. MEAD

Chief Engineer, Bridges and Grade Crossings, New Jersey
Public Utility Commission, Newark

FIRE started by lightning on the night of Sunday, July 22, destroyed a very old wooden bridge over the Delaware River at Stockton, N. J. Because of the great age of the structure as well as the nature of its destruction the following notes on it may be of interest.

Records show that the bridge was originally erected in 1812-13. This would make it 110 years old if it was not rebuilt at a later date; there is no record of such rebuilding. No information can be found as to the name of the builder or other pertinent facts.

Since 1911, when the writer first saw the bridge, only such repairs have been made as were necessary to keep it in service. In recent years it has been limited to

floor and fell into the river—a direct consequence of the driver's failure to heed the load-limiting signs. Many of the floorbeams over which the truck had passed were found broken. Repairs were made and the bridge was again opened to traffic under the one-ton limitation.

The drawings reproduced in Fig. 1 herewith show the principal features of the construction of the bridge, as plotted from a survey made in 1914. The spacing of the piers that supported the six river spans was quite irregular. Most of the old timber in the bridge was hemlock. The masonry was random. It is believed that the piers were probably founded on timber grillage and the abutments on rock. The truss intersections were held together with hand-shaved oak treenails 1½ in. in diameter.

The fire, which resulted from a lightning stroke on July 22, burned up five of the spans. The New Jersey end span was dragged from its abutment when the ad-

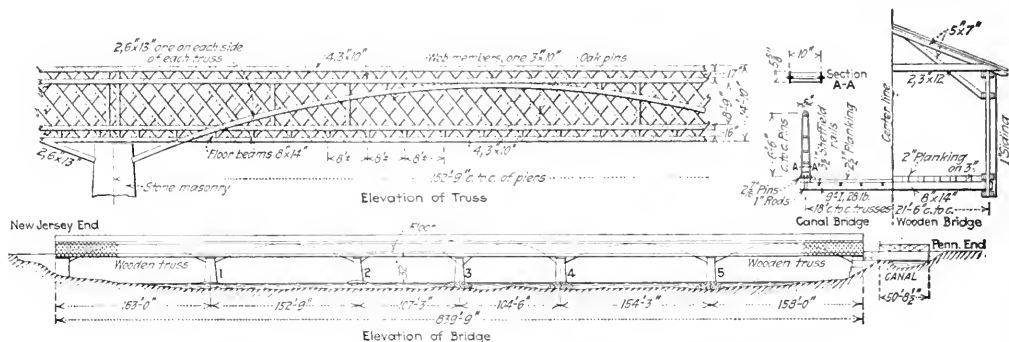

FIG. 1—CHARACTERISTICS OF TIMBER SPANS AND IRON APPROACH SPAN OVER PENNSYLVANIA CANAL

loads of one ton. A year ago a Packard truck having a nominal capacity of $3\frac{1}{2}$ tons, carrying a load of miscellaneous groceries, attempted to cross the bridge from the Pennsylvania end. It reached the second span from the New Jersey end, where it broke through the

joining span collapsed; this was due to the continuous truss construction. A number of men who were fighting the fire fell with the span, some being injured. The stonework of the piers was spalled off by the heat 1 or 2 in. deep, and the tops were injured.

FIG. 2—STOCKTON BRIDGE, BEFORE AND AFTER THE FIRE

A—Interior view showing one of the trusses. B—General view of the bridge. C—Wreckage of the New Jersey Shore span.
D—Ruins of the river piers.

Engineering Literature

A MONTHLY REVIEW OF BOOKS AND A LISTING OF NEW PUBLICATIONS

Mechanics of the Human Body

REVIEWED BY GEORGE C. WHIPPLE

Professor of Sanitary Engineering, Harvard University,
Cambridge, Mass.

LE MOTEUR HUMAIN et les Bases Scientifiques du Travail Professionnel—Par Jules Amar, Directeur du Laboratoire de Recherches sur le Travail Professionnel au Conservatoire National des Arts et Métiers, Docteur des Sciences, Membre Correspondant de L'Académie des Sciences de Lisbonne; avec une Préface de Henry Le Chatelier, Membre de L'Institut, Inspecteur Général des Mines, Professeur à la Sorbonne. 2nd Edition. Paris: Donod. Cloth; 6x7 in.; pp. 690; 324 line cuts and halftones.

This is an interesting discussion of the human body from a mechanical standpoint. It treats of anatomy and human energy. It describes many sorts of experiments in the physiological laboratory and the application of mechanical principles to human labor. Compared with other motors, a laboring man is rated as having about one-seventh horse-power and an efficiency of 30 per cent. These figures mean little because they are apparently based on laboratory experiments of short duration, do not take into account cumulative fatigue, fatigue of particular muscles, mental fatigue, and other factors which are matters of importance.

Nevertheless, the book is an interesting one as showing the care with which the human mechanism is now being studied by physiologists.

River and Harbor Engineering

THE HYDRAULIC PRINCIPLES GOVERNING RIVER AND HARBOR CONSTRUCTION—By Curtis McE. Townsend, Colonel, United States Army (Retired), M. Am. Soc. C. E., Late President Mississippi River Commission. (Engineering Science Series.) New York: The Macmillan Co. Cloth; 6x9 in.; pp. 189; 5 line cuts. \$2.60.

The literature in English of river and harbor hydraulics is limited to a very few books and to the proceedings of the technical societies, periodical literature and the report of the Corps of Engineers of the United States Army. Colonel Townsend has therefore done excellent service in setting down the results of his forty years of experience in this kind of engineering work. No one in the United States certainly is better qualified to write on the subject than he.

The book is devoted more largely to rivers than it is to harbors. It traces the geologic and hydrologic history of rivers, outlines the laws governing the flow of water in open channels, analyzes the question of sediment flow and describes methods of flood prediction. All this is the hydrologic side of the river and is not concerned with man's control of it. The next division is on the control. Here the methods of regulation are described in some detail under the heads of Bank Construction and Bank Protection, Improvement by Canalization and Dredging. Three chapters take up the question of flood and navigation control, particularly as relating to the Mississippi River, and repeat Colonel Townsend's well-known views regarding the proper method of control of the Mississippi. There is, moreover, an extended historical-descriptive chapter on flood protection in the various rivers of the world. A chapter on harbors, estuaries, and the

mouths of rivers and harbors is followed by a final chapter on the economics of water transportation which is so definite and concise that it would be well if it were circulated to be read by all of the violent enthusiasts of waterways versus railroads. Colonel Townsend is by no means an antagonist of river transportation, but he sees and sets down clearly the conditions which govern such a development.

River regulation is a fascinating branch of engineering which few engineers outside of those in government service have occasion to practice. Moreover, it is a science in which experience counts more than theory. Any engineer, therefore, who has such work to do would do well to fortify himself with the record of experience here set down and thereby add to his own theory.

A.I.A. Promotes Appreciation of the Arts

THE SIGNIFICANCE OF THE FINE ARTS—Published Under the Direction of the Committee on Education of the American Institute of Architects, Boston: Marshall Jones Co. Cloth; 6x9 in.; pp. 481; 128 halftone plates. \$3.50; or edition de luxe, \$7.50.

To those engineers who ask themselves, What is art? and who wish for a concrete rather than an abstract answer this book should be welcome. It should be all the more welcome because architecture, with which the engineer has so much to do, takes up the larger part of the volume—the book was planned by a committee of the American Institute of Architects.

The specific object of the book is to arouse general "interest in the fine arts" and to create "a better understanding and appreciation of them." Particular attention is given to showing the relation of art to life, historically and today, and, more specifically, how the variations in the arts, and how the different styles of architecture, reflect, and were "developed from, the customs, habits and social and religious life of the several peoples."

By periods, architecture is distributed as follows: Introduction, George C. Nimmons, for the Committee on Education, A. I. A.; Classical, H. Howard Walker, Boston; Middle Ages, Ralph Adams Cram, Boston; Renaissance, H. Van Buren Magonigle, New York; Modern, Paul P. Cret, Philadelphia. A point of importance to engineers is the statement by Mr. Nimmons, that emphasis is placed on "those vital principles of design and construction [italics ours] which not only govern all good architecture, but should also influence the character of all other arts and every manufactured product and material thing that human hands can make." The chapter on Modern Architecture, Mr. Nimmons well says, "describes new methods of construction, the new problems of design, the revolutionizing of many old modes of life by the new era of mechanical development, and the interesting reflection of the very pronounced characteristics of the people of today in their buildings."

The Allied Arts are necessarily treated more briefly, but fully enough to give their main significance to the

engineer—and it is to be noted that a hope of more detailed treatment of these subjects later on is expressed. The six topics in Part II are: Sculpture, by Lorado Taft; Painting, Bryson Burroughs; Landscape Design, F. L. Olmsted; City Planning, Edward H. Bennett; Industrial Arts, Huger Elliott; Music, T. W. Surette. Messrs. Olmsted and Bennett are well known to many engineers as experienced practitioners in the two fields which they have reviewed, Mr. Bennett having been associated with the late D. H. Burnham, architect and city planner, and Mr. Olmsted having been long established in both landscape and city planning work.

Well chosen illustrations abound in the various sections of the book and each has a well selected bibliography which will enable the reader to pursue the subject as much farther as he may wish. Altogether the book is a commendable one and should do much to extend the knowledge and appreciation of architecture, the other fine arts and the industrial arts.

Two Notable Books on Town Planning

TOWNS AND TOWN PLANNING, ANCIENT AND MODERN—By T. Harold Hughes, Fellow of the Surveyors' Institution, Associate of the Royal Institute of British Architects, and E. A. G. Lamborn, Hon. M. A. Oxon. New York: Oxford University Press, American Branch. Boards, cloth back: 8x10 in.; pp. 156; colored frontispiece, folding map and 89 line cuts and halftones. \$5.

SITE PLANNING IN PRACTICE: An Investigation of the Principles of Housing Estate Development—By F. Longstreth Thompson, B.Sc. (Eng., London), Assoc. M. Inst. C. E., Late Assistant Architect to the Housing Department, Ministry of Health; with a Foreword by Raymond Unwin, F.R.B.A., Chief Architect, Housing Department, Ministry of Health. London: Henry Frowde and Hodder & Stoughton. New York: Oxford University Press, American Branch. 16s.; \$5.35.

Engineers, architects, and students who are taking up city planning for the first time, or who wish to enlarge or freshen their knowledge of the historic backgrounds of the art and the way it has been influenced by the habits, customs, and spirit of the different periods of history, will find "Towns and Town Planning, Ancient and Modern" useful, interesting, and suggestive. The book surveys town planning the world over from the earliest known examples of ancient times to the present day.

From the book one may learn, either by direct statement or deduction, how largely military considerations governed town planning to and through the Middle Ages; how the ending of the need for walled towns led to a change from vertical to horizontal expansion as populations increased; how a desire to increase land rents encouraged monks and kings to expand town areas by turning agriculture into urban areas, at the same time making villeins and serfs free citizens, through grants in many of the mediaeval borough and city charters; how the "industrial revolution" created city barracks and slums in the prevention or amelioration of which neither the industrial nor spiritual lords of the day took thought, except to oppose—the first having no interest except in factory profits, and the second feeling more concern for proprietors than for people, and for rents from overcrowded, insanitary dwellings than for reforms of any kind; and how in the long process of time it finally was realized that cities exist for the people rather than for emperors and kings, or military, industrial, or religious overlords.

Of all the kingly and military figures chronicled in this history of town planning, Edward I stands out most prominently through the towns he caused to be planned and built in his French, English, and Welsh domains. Louis XIV and Leñôtre at Versailles, Wash-

ington and L'Enfant at Washington, Napoleon III and Baron Haussman at Paris, Howard in his visions of the Garden City, and Cadbury and Lever and others in making the vision a reality, and Burnham in his Chicago plan are some of the notable figures since Edward I that appear in this inspiring survey of town planning. In the field of legislation, Sweden as early as 1734 and in more detail in 1874, stands out. Germany took a place of its own, both in theory and practice, soon after Sweden's example. Other high spots are the British Town Planning Act of 1909, due largely to John Burns and Lloyd George (although the former is given no credit in this book) and recent French legislation. Although the book mentions the recent sweep of town planning in America it takes no account of the large volume of state legislation which has given town planning and zoning a legal status here. Nor does it take into account vertical city expansion in America made possible by steel and steel-concrete construction and the high-speed elevator, with the serious problems in city planning thus created.

"Site Planning in Practice," by the London partner of Thomas Adams, is a book of quite a different sort from the one we have been considering, but in a sense it supplements the final chapter of "Towns and Town Planning," which is devoted to current and future town planning. Primarily, the second book is devoted to that part of housing which plans street, block and house-group layouts; but this also includes a consideration, mostly sketchy, of water supply, sewerage and sewage disposal, schools and other public buildings, parks, open places, and main highways. Transportation is even more lightly sketched, to which no serious objection can be made in view of the main topic of the book, but if water supply and sewerage are to be included, why not gas and electric lighting?

The greatest usefulness of the second book lies in its analysis, by text and diagram, and with halftone illustrations where feasible, of the economics, hygienics (light and air) and in less degree the esthetics, of placing houses upon land and providing access to and from them. The facts, figures and illustrations on this main topic will repay study by American town planners, even though some of the governing conditions in England are so different from those in America.

It should be understood that the volume has a still further limitation in that it is confined almost wholly to what may be termed liberal-housing developments under a two-story height limit. That is, the authors base their detailed studies on the new British housing limits of twelve families to the acre (or sixteen houses if 25 per cent is allowed for streets and open spaces). This is liberal compared either with previous two-story house practice in England or with American multi-story tenement and apartment houses.

The attention that the author seems compelled to give to utilizing almost every foot of frontage, even to the extent of almost or quite continuous front walls, is distressing unless one remembers that this twelve-family limit gives every family a fairly deep though narrow front or back yard (considered sufficient to produce an ample supply of vegetables) and until it is realized that the real cost of housing includes all the attendant outlay for: (1) Land, including (a) the house lot and (b) streets and open spaces, and (2) Pavements, curbs, sidewalks, house walks, water and

gas mains, sewers, wires for electric and telephone service. As to how these various elements affect cost, Mr. Thompson takes into account, in his view cost figures, only land, road and sewer construction. Presumably he leaves the cost-elements of the other utilities to be covered in the charges for water, gas, electricity and telephones; or even assumes that in most cases the householders will do without telephones and in many without electricity—neither of which would be expected in most American twelve-family-per-acre new housing developments.

The author gives no evidence of having consulted "Industrial Housing" by Morris Knowles (see these columns, Oct. 21, 1920, p. 807), in which the economics of housing developments, including land, street and utility cost elements, is worked out in detail and numerous examples of site planning are given.

Notwithstanding the usual limitations of a book written chiefly for use in a single country (which applies more particularly to Mr. Thompson's Site Planning) both these volumes deserve wide attention in this country; particularly should they be given immediate place in the libraries of town planning engineers, planning commissions, colleges and municipalities.

Ups and Downs of Business and Labor

BUSINESS CYCLES AND UNEMPLOYMENT Reports and Recommendations of a Committee of the President's Conference on Unemployment, Including an Investigation Made Under the Auspices of the National Bureau of Economic Research. With a Foreword by Herbert Hoover. New York and London: McGraw-Hill Book Co. Cloth; 6x9 in.; pp. 405; diagrams. \$4.

Growing out of the work of the President's conference on unemployment, which met in Washington in September, 1921, this report presents the results of an exhaustive investigation together with certain practical and constructive suggestions designed to stabilize business and industry so as to prevent the waste and suffering now brought about by the valleys in the so-called business cycle.

Although the immediate problem of the committee was to cope with the situation then existing, it was recognized that when business depression has come it is too late for any measures except those of relief for the unemployed, and that, if we are to follow a policy of prevention rather than of mitigation, it will be necessary to develop the exercise of foresight and to provide means to maintain greater business stability.

As a result of its studies the committee is confident that the destructive extremes of business cycles can in a large measure be controlled.

In undertaking its study, however, it found that little could be accomplished toward a definite constructive program until the fundamental facts upon which action must be based are made available in current and comparable form. A considerable part of its recommendation concerns means whereby data may be accumulated.

The general methods by which the business cycle may be controlled are outlined by the committee as (1) control of credit expansion by banks generally, (2) possible control of inflation by the Federal Reserve System, (3) control by individual business men of the expansion of their own industries, (4) control of public and private construction, including construction by public utilities at or near the peak of the business cycle, (5) construction of public works in the depression, (6) unemployment reserve fund, (7) federal and state employment bureaus.

Upon these general principles, that is, the need for facts and methods of control, the committee makes ten recommendations. It sets forth also six questions for discussion, addressed respectively to business men, to bankers, to managers of public utilities and public service commissions, to wage earners, to engineers and to citizens' organizations, designed to procure from each its contribution toward the solution of the problem.

Following the formal report of the committee, the greater part of the book is given up to a series of papers discussing the relation of business cycles to unemployment and proposed remedies for present conditions. These have been prepared by authorities in the several fields of economics and social science, and include the following:

Business Cycles, by Wesley C. Mitchell, National Bureau of Economic Research; Individual Industries and Enterprises in the Business Cycle, Frederick R. Macaulay, National Bureau of Economic Research; Economic Losses Caused by Business Cycles, Wesley C. Mitchell and Willford I. King, National Bureau of Economic Research; What the Present Statistics of Employment Show, William A. Berridge, Brown University; Under-Employment, Paul F. Brissenden, Columbia University; Changes in Employment in the Principal Industrial Fields, Jan. 1, 1920, to March 31, 1922, Willford I. King, National Bureau of Economic Research; Effect of Unemployment Upon the Worker and His Family, Stuart A. Rice, Columbia University;

The Various Kinds of Remedies Proposed, by Wesley C. Mitchell, National Bureau of Economic Research; Methods of Stabilizing Production and Distribution, Sanford E. Thompson, The Thompson & Lichtner Co., Engineers, Boston; Problem of "Cancellation," Gilbert H. Montague of the New York Bar; Methods of Stabilizing Work in the Building Industries, Ernest S. Bradford, vice-president of the American Statistical Association; Stability of Railway Operations, Julius H. Parmelee, Director of the Bureau of Railway Economics; Long-range Planning of Public Works, Otto T. Mallory, Member Pennsylvania State Industrial Board; Financial Devices for Controlling or Mitigating the Severity of Business Cycles, Thomas Sewall Adams, Yale University; Public Employment Offices and Unemployment, Shelby M. Harrison, Director of Department of Surveys and Exhibits, Russell Sage Foundation; Trade Union Out-of-work Benefits, John B. Andrews, Secretary of the American Association for Labor Legislation; Unemployment Insurance, Leo Wolman, New School for Social Research; Charting the Course of Employment, Mary Van Kleeck, Director of the Department of Industrial Studies, Russell Sage Foundation; Statistical Indexes of Business Conditions and Their Uses, Oswald W. Knauth, National Bureau of Economic Research; Various Devices used for Stabilizing Business, by a Committee of the Federated American Engineering Societies.

These papers are effectively supplemented by tabular and graphical matter and constitute a unique compendium of data concerning the many factors that enter into modern social and economical development.

United States Bureau of Public Roads

THE BUREAU OF PUBLIC ROADS, Its History, Activity and Organization—By W. Stull Holt. Service Monograph of the United States Government, No. 28. Baltimore, Md.: Johns Hopkins Press. Cloth; 6x9 in.; pp. 123. \$1.

In the last few years the work of the Bureau of Public Roads has grown so much and its influence on highway development has become so great as to make it desirable for engineers and others to have a handy volume like this one to which they can turn for information. Between its covers answers may be found to most inquiries likely to be made concerning organization, practices, laws and finances. The Federal Aid Acts are reprinted.

PUBLICATIONS RECEIVED

THE ENGINEERING ASSOCIATION OF MALAY, organized in 1920, published creditable *Transactions* a few months ago and announces that a similar volume for 1922-23 is now ready. The 1920-21 volume contains five papers, with folding plates, on Malayan water-supply works, railways and wharves, and a paper on Deterioration of Structures in Sea Water. Four of the papers are by members and associate members of the Institution of Civil Engineers and one is by an Assoc. M. Inst. Meeh. E. (Serembam, Federated Malay States: F. M. Corkill, honorary secretary).

THE MILWAUKEE ACTIVATED-SLUDGE PLANT is briefly described in a pamphlet issued by the Sewerage Commission of Milwaukee, Wis.

SIX PAPERS ON SEWAGE TREATMENT and one on sewerage maintenance are included in the *Proceedings* of the New Jersey Sewage Works Association for the two years 1922 and 1923. Work at the sewage experiment sub-station at New Brunswick, N. J., is the subject of two papers. John R. Downes, of the Plainfield joint sewage-works, discusses odors. A report of a talk on Superfluous Sewage Treatment Works, by M. N. Baker, associate editor *Engineering News-Record*, includes a summary of attempts to treat sewage by electrolysis and comments on the plans to treat the sewage of Trenton by the direct-oxidation process, with particular reference to the Hirst-Potts charges, which had been filed with Governor Silzer shortly before the 1923 meeting of the association. (Myron E. Fuller, secretary-treasurer, 36 Mt. Airy Ave., Philadelphia, Pa.; \$1.)

SYSTEMATIC ANTI-MALARIA WORK through the control of mosquito breeding has now been carried on in South Carolina since 1919 under a tripartite agreement between the U. S. Public Health Service, the International Health Board and the South Carolina State Board of Health. An illustrated pamphlet reviewing the work, written by L. M. Fisher, associate sanitary engineer, U. S. P. H. S., may be obtained on request from the State Health Officer, Columbia, S. C.

NOVEL EXPERIMENTS designed to lead up to the design of an intensity rain gage, apparently for use where heavy rainfalls occur, are described in a paper on The Experimental Development of an Automatic Integrating "Intensity" Rain-Gage Without Clockwork, by John W. Meares, C. I. E., M. Inst. C. E. The principle utilized was that the horizontal trajectory of water discharged from a small jet connected with the funnel tube of a rain gage would vary with the head in the gage, which in turn would depend on the intensity of the rainfall. Having determined these trajectories for various intensities, receptacles are located accordingly and, presumably, the depths or volumes caught in each receptacle are measured and a record made in terms of intensities. The author retired from the British Indian Service before his studies had been completed to his satisfaction, but states that installation of the apparatus on a working scale in India is under way; also that he has refrained from taking out patents. (London: Institution of Civil Engineers; Selected Engineering Papers, 1923, No. 2.)

"COMMERCIAL PREPAREDNESS" and "Greater Prosperity Through Greater Foreign Trade" are slogans that appear on the cover and title page of the proceedings of the Tenth National Foreign Trade Convention, held at New Orleans in May of this year. (India House, Hanover Square, New York City.)

THE WATER-POWER SITUATION IN NORTH CAROLINA is outlined in circular No. 6 of the water resources division of the North Carolina Geological and Economic Survey. Besides supplementing and bringing to date similar information given in Circular No. 2 this one enumerates the factors which are tending toward drawing on sources for power supply outside the state.

ENGINEERS OF HIGHWAY DESIGN will find suggestive information in the pamphlet of 48 pp. on economies of

highway grades, published by the Engineering Experiment Station of Iowa State College, Ames, Ia. From experiments made in 1919, Prof. T. R. Agg arrives at certain tentative conclusions respecting allowable expenditure for reducing highway grades.

THE MINISTER OF PUBLIC WORKS OF ITALY through the Council of Public Waters (Consiglio Superiore Delle Acque Pubbliche, Rome, Italy) issues in the form of "annali" excellent reviews of water-works practice in Italy. The latest one, Vol. 5 of 1923, second section, has some beautiful views of the Tirso Dam, the highest multiple-arch dam in the world, recently described in *Engineering News-Record*; articles on rock tunnels, design of multiple arches and hydro-electric developments in Italy. The work is under the charge of the eminent Italian engineer, Carlo Bonomi.

NO ONE VOLUME contains more valuable current data on concrete and reinforced concrete than the *Proceedings* of the American Concrete Institute. Volume 19 of that society, giving the *Proceedings* of the nineteenth annual convention, is now available through the secretary, Harvey Whipple, Friesma Building, Detroit, Mich. It contains in addition to the numerous committee reports of the society a number of well illustrated papers in all fields of concrete design and construction.

New Books and Revised Editions

LE CALCUL RATIONNEL DES ÉLÉMENTS D'UNE CONDUITE FORCÉE EN MÉTAL: Sur base de la Théorie de San Rendimento Economique Maximum—Par Paul P.-Santo Rini, Ingénieur E.P.Z., Ingénieur en Chef de la "Société Anonyme d'Etudes et d'Enterprises," Athens, Grenoble, France; J. Rey. Paper; 6x9 in.; pp. 39; 7 line cuts.

A new printing of a study first published in 1921. THE DESIRED REGIONAL PLANNING SCHEME [Chester & Flintshire]: Report Prepared for the Joint Committee of Local Authorities by Patrick Abercrombie, Sydney Kelley and Theodore Tyffe. Liverpool: University Press. London: Hodder & Stoughton. Paper; 10x12 in.; pp. 67; halftone plates and folding maps, some of the latter large and in colors. 7½s. net.

Follows the same general line as the Doncaster report noted at length in these columns July 19, p. 110, but is of far more general interest because Chester and Flint afford remarkable examples of Roman and mediaeval town planning, while Chester has a notable cathedral and the ruins of Flint and Hawarden Castles, as well as other ruins, to add to the attractions of the region considered in the planning scheme. Flint, the report says, was "laid out by Edward I. in 1277, as an appendage to his mighty castle and has preserved its mediaeval plan almost intact." Edward I. it may be added, was one of the greatest town planners the world has known.

ESTIMATING BUILDING COSTS.—By Charles F. Dingman, M. Am. Soc. C. E., M. Am. Soc. M. E., N. J. Soc. A. New York and London: McGraw-Hill Book Co. Flexible cloth; 4x7 in.; pp. 240. \$2.50.

GERMANY'S CAPACITY TO PAY: A Study of the Reparation Problem.—By Harold G. Moulton and Constantine E. McGuire, with the Aid of the Council and Staff of the Institute of Economics. New York and London: McGraw-Hill Book Co. Cloth; 5x8 in.; pp. 384; 7 line cuts. \$2.

HÜTTE: DES INGENIEUREN TASCHENBUCH—Herausgegeben vom Akademischen Verein Hütte, E. V. in Berlin. 24 auflage, II Band. Berlin: Wilhelm Ernst & Sohn. Flexible cloth; 6x8 in.; pp. 1288. Illustrated. \$2 in Germany.

This volume of the new (24th) edition of the well known Hütte deals, among other things, with steam boilers, steam turbines, metal working machines, ship design, propellers, etc., automobiles, and some phases of electrical engineering. INDUSTRIAL AMERICA IN THE WORLD WAR: The Strategy Behind the Line, 1917-1918.—By Grosvenor B. Clarkson, Late Director of the United States Council of National Defense, with an Introduction by Georges Clemenceau, Boston and New York: Houghton, Mifflin Co. Cloth; 6x9 in.; pp. XXIII +573; 25 halftone plates of individual and group portraits. \$6.

INDUSTRIAL DEMOCRACY: A Plan for Its Achievement.—By Glenn E. Plumb and William G. Roylance. New York: B. W. Huebsch, Inc. Cloth; 6x8 in.; pp. 359; frontispiece portrait of senior author. \$2.

OIL FLOW-VISCOSITY AND HEAT TRANSFER: Including Crude and Fuel Oil Viscosity Temperature Charts, Pipe Line Temperature Drop Charts, Commercial Pipe Coefficient Chart, Pressure Loss in Fittings Chart, and Formula for Testing Oil Heaters, Coolers and Heat Interchangers.—By R. S. Danforth. Assoc. Mem. Am. Soc. C. E. San Francisco, Calif.: The Author. 5x5.5 halftone plates. Thick paper, cloth back; 6x9 in.; pp. 16, besides plates; \$2.

THE VENTILATION OF PUBLIC BUILDINGS.—By Robert Boyle, London: Robert Boyle & Son. Boards; 6x8; pp. 50; line cuts. 6s.

Excerpts from (1) reports of Royal Commissions and Select Committees on Ventilation Appointed by the British Houses of Parliament and (2) from other sources, mostly British, favoring natural rather than mechanical ventilation. Most of the excerpts are unedited. A one-sided publication, likely to mislead the uninformed.

TABELLEN UND DIAGRAMME FÜR WASSERDAMPF—Von Dr. Phil. Dr.-Ing. E. H. Osc. Knoblauch, Dipl.-Ing. E. Ralsch, and Dipl.-Ing. H. Haasen. Munich and Berlin: R. Oldenbourg. Paper; 8x10 in.; pp. 32; 3 folding diagrams. 50c.

Letters to the Editor

This department aims to be a forum for the discussion of the views of engineers and contractors. The range of interest should be as wide as possible. Contributors are, therefore, asked to make their letters short.

Soil Tests Essential to Foundation Design

Sir—Having acted, in an advisory capacity, for the Westinghouse Co., in connection with the underpinning of the foundations for their new building in Philadelphia, the writer was glad to see the full description of this interesting work in your issue of August 2, 1923, p. 192.

The ingenious plan adopted by the contractors, and the thorough manner in which the work was carried out, reflect much credit on their engineering and business methods. It is perhaps worth while to add that the strength of the U-bars, by which the new needle beams are attached to the footing slabs, was fully tested by actual experiment in the field.

The principal lesson to be learned from this partial failure, is of course the need, in all cases, of making thorough soil tests, before deciding on the methods to be used in foundations.

Very truly yours,

HENRY GOLDMARK,
Consulting Engineer.

New York City, Aug. 8, 1923.

Subways and Building Heights

Sir—In connection with the question of building heights mentioned in the editorial in your issue of July 12, that the cities are doing is described in the Chicago *Herald & Examiner* of July 16 as "Chasing Their Tails." I enclose copy of this editorial.

So far as light, ventilation, architecture and beauty are concerned, these considerations, important though they be, can be laid aside. The difficulty of transportation cannot be laid aside and I do not agree with you when you say that these difficulties have never been made argument in height limitation, but I do agree that they have not received the study which they should. It seems obvious and self-evident that there should be a proper relation between the width of streets serving buildings and the intensity of occupation of those buildings. A tall building to be served by a narrow street is as I see it a matter of plain stupidity.

Building subways is a tremendous burden, in one way or another, on a community and it does not solve the problem. It is, in fact, just one step in the process of chasing our own tails.

Chicago, Ill., July 17.

B. F. AFFLECK,
President, Universal Portland Cement Co.

[The editorial from the *Herald & Examiner* is as follows:

"When a dog chases his tail we laugh at canine stupidity. 'But when a government announces, through its Navy Department, that an armor has been invented which no shell can pierce, and then follows it with a War Department proclamation of a shell no armor can stop, we call it progress.

"So it is economic progress when wages are raised because prices are high, and then high wages send prices higher, so the wages cannot catch up with it.

"The Kelker report on 'Unified Transportation' made to the Chicago city council recited the fact that in New York City recently a new subway line was built beneath a certain street. Within the year a single building in a single block was built so great in size that it immediately absorbed one-third of the capacity of the new subway.

"That is no reason we should not hasten the building of subways in Chicago. But it is possible that even through subways we shall not travel to the millennium."—EDITOR.]

Computing Motor-Vehicle Fees

Sir—With reference to Mr. Barnett's article on "A Logical Method of Computing Motor-Vehicle Fees," *Engineering News-Record*, May 3, 1923, p. 797, it is desirable at the outset to get the fundamental facts of the question clearly in mind. Mr. Barnett speaks of annual cost and first cost, giving annual cost as the sum of three items, Interest + Maintenance + Sinking Fund—which is correct, but includes first cost, it being assumed that interest and sinking fund is for retiring bonds issued for the improvement. Bonds should not, of course, be issued for maintenance. The writer also assumes that the motor-vehicle owner does not pay the complete first cost of the system. Naturally, the general public as a class, being an indirect beneficiary, should share to some extent in such cost, but not in costs of maintenance.

To start then, where Mr. Barnett does, and with the above in mind, annual cost is the sum of Interest + Maintenance + Sinking Fund Payment. Let us condense this into two items, (1) Maintenance + (2) Interest and Sinking Fund Charge. Now what is maintenance? It is that branch of highway service applied constantly to the system which makes good each defect and deterioration as it occurs, reconstructing where necessary, and in short keeping the improvement or system in the condition equal to that in which it was when constructed. Consequently improvements so maintained are permanent, and strictly speaking, wear-proof. The cost of maintenance is the cost of such service. The second item of cost relates to the cost of the original construction.

Now, then, the motor vehicle owner must be assessed for the service which renders the improvement wear-proof, after which he must also share in paying the cost of original construction. This being true, why, then, after the first mentioned service has been paid for, should he be further penalized for producing impact on a road which is already made immune to impact, and is wear-proof (because maintained)?

Where an improvement is provided for a community, its cost must be shared according to the capacity of each individual to utilize or enjoy such improvement, that is, provided it is equally free to their use and enjoyment. Damage to the improvement must be made good by the individual who actually commits the damage, and not by the community according to the capacity of each one to do such damage. Thus, we arrive at the conclusion: for interest and sinking fund payment, each vehicle must pay according to capacity to utilize the system; for maintenance, each vehicle must pay according to the damage it actually does. The sum of the payments makes up the total annual cost.

For all practical purposes the capacity of a vehicle to utilize the improvement varies as to load carried and the speed, for which the fee becomes,

$$\text{Fee} = C \times L \times S = \frac{C \times L \times HP}{W}$$

where C is a constant, L = load above springs, HP = horsepower, and W = total weight loaded. This gives as the fee of the three-ton truck a sum about 50 per cent in excess of the Ford touring car for its item.

So far as the damage done is concerned, Mr. Barnett's formula only gives capacity to produce impact and therefore damage, and hence is useless unless distance traveled is taken into account. There must also be considerable doubt as to the effect of resiliency of tires, and notwithstanding tests made by the Bureau of Public Roads resulting in a factor of 7 for the resiliency of a pneumatic tire relative to the solid tire, it certainly would seem more on the side of safety and conservatism to eliminate this factor for the present, until the actual facts have been demonstrated by more extended field test. Other factors such as applying of brakes, and shifting gears are items whose effect cannot well be calculated. Such uncertain factors are to a greater or less degree taken care of through such a tax as the gasoline tax. As all motorists know, the consumption of fuel is affected very appreciably by condition of tires, speed, shifting of gears, applying of brakes, etc.

While the writer does not believe that the total cost of

maintenance should be met by a gasoline tax, he does believe that between 50 and 75 per cent of it should be, and the balance should be met by a vehicle fee. For those using gasoline for purposes other than the propelling of motor vehicles on the roads, a system of rebates will, it is believed, be worked out.

With a gasoline tax, the items of cost to be met by a license fee become: (1) Maintenance-Gas Tax + (2) Interest and Sinking Fund. The first is met by Mr. Barnett's formula for fee, the second by the one above given, and the sum of the two is the license fee. The constant in the formula should in each case be worked out by assuming an arbitrary value as the fee for a particular car, and then adjusting to give the result desired for the total. The average, as taken by Mr. Barnett, might not be a point on the curve, unless average weight, horsepower, etc., were carefully worked out, which would be laborious and involve useless effort.

Taking Mr. Barnett's figures and assuming that, of the \$6,000,000 total, \$1,000,000 is required annually for maintenance, of which latter \$2,800,000 may be raised by a gasoline tax (given approximately by a 2c. tax on the basis of 350,000 cars) we then have, to be raised by Mr. Barnett's formula, \$1,000,000 - \$2,800,000 = \$1,200,000 and the balance, \$2,000,000, to be raised by the formula proposed by the writer, then assuming Mr. Barnett's figures for average values to be correct and neglecting resiliency,

$$C \text{ (in Barnett penalty formula)} = \frac{1,200,000 \times 3,000}{350,000 \times 1,600 \times 500 \times 30} = 0.000428 \text{ (approx.)}$$

$$C \text{ (in writer's formula)} = \frac{2,000,000 \times 3,000}{350,000 \times 1,600 \times 30} = 0.357 \text{ (approx.)}$$

For the Ford Touring Car:

$$\text{Penalty Fee} = \frac{0.000428 \times 1,450 \times 300 \times 25}{2,500} = \$1.87$$

$$\text{Utilization Fee} = \frac{0.357 \times 1,450 \times 25}{2,500} = \$5.17$$

$$\text{Total License Fee} = \$7.04, \text{ say } \$7$$

For the 3-Ton Truck:

$$\text{Penalty Fee} = \frac{0.000428 \times 7,200 \times 1,200 \times 35}{12,000} = \$10.80$$

$$\text{Utilization Fee} = \frac{0.357 \times 7,200 \times 35}{12,000} = 7.50$$

$$\text{Total } \$18.30, \text{ say } \$18.25$$

This compares with \$8.50 and \$49.30 respectively as given by the Barnett formula.

J. F. SEILER,

Engineer of Bridges, Wyoming State Highway Dept.
Cheyenne, Wyo.,
June 19, 1923.

[Copy of this letter was sent to Mr. Barnett for comment and his reply follows.—EDITOR.]

Sir—Mr. Seiler's comments on my article under the caption of "A Logical Method of Computing Motor-Vehicle Fees" are not without merit. It is admitted that no one form of tax will equitably meet all the requirements for a highway development program. It would be well, however, to confine our attention to one subject at a time and to leave for other and separate discussions such collateral issues as the distribution of construction costs between property owners and users of the road, or that of the gasoline tax sales, or whether maintenance should be defined so as to include replacement and reconstruction.

The underlying idea of my original article was that of distributing a given tax burden among motor vehicles in such a way that greater equity to the owners would be assured. The method there proposed applies equally well whether the fees are used solely for maintenance or for the entire annual cost of the road. Neither does this proposed method preclude the adoption of a gasoline sales tax in conjunction therewith.

The fact that motor traffic—through reduction of operating cost and in the saving of time—is the greatest beneficiary of, and is also the largest factor in, producing wear

on roads, gives the best reason for collecting from such traffic, by means of license fees, the equivalent of a major portion of the annual costs. We start from the basis that a certain sum of money is to be raised by collecting motor license fees from motor vehicle owners. This sum may be sufficient to pay the entire annual costs or only some part thereof, such as maintenance. That is a matter of state policy and is beyond this discussion. The immediate problem is then so to distribute these fees among the motor vehicle owners that some fairness and equity may prevail.

If we take the use of the road as a basis for assessing fees on vehicles, we are confronted with the difficulty that we cannot determine in advance the amount of such usage. We should need to know not only the distance traveled, but also the load carried. Again if the mere use of the road were the test, then the vehicles that produce the same ton-mileage of transportation should be assessed equally. However, it is readily seen that if these vehicles are of different sizes and types some of them will produce more wear upon the roads than others and that it would then be necessary to devise some means of assessing against the more destructive vehicles a heavier penalty. The gasoline would, of course, afford some partial measure for the use of the road as such usage occurs. But a gasoline-sales tax is not a motor-vehicle tax and so must be left for separate discussion. We are here directly concerned with the proposition of assessing license fees against motor vehicles. The practicable basis, the basis that will give some approach to equity for such assessments, is the amount of wear or damage done the road by any vehicle.

The wear on the road is largely due to impact, which all vehicles produce to a greater or less extent. While it is not practicable to measure in advance the actual impact, or rather to measure the total of a series of such impacts as the vehicle moves over a stretch of the road, it is, however, entirely feasible to determine in advance the capacity of the vehicle for producing impact. It is thus seen that the practicable thing, the tangible thing that we can lay hold of, is the capacity of vehicles to produce impact. The license fees based upon such capacity will be a closer approximation to an equitable standard than anything we now have.

The determination of impact stresses must necessarily include the properties of the body absorbing the impact, as well as the amount of energy stored up in the motor vehicle springs which produces the impact. To leave out the factor of resiliency is to ignore the fundamental principles of mechanics underlying the phenomena of impact. Furthermore there is no reason at this time to discredit or minimize the results of the investigation carried on by the Bureau of Public Roads, for as yet we have no better information nor more reliable data upon which to base our conclusions.

Jefferson City, Mo.,

R. C. BARNETT.

July 2, 1923.

Swiss Rack-Rail and Cable Mountain Lines

Steep-grade mountain railways operated by rack-rail or cable, in Switzerland, aggregate 64 in number and about 98 miles in length, according to a paper in the *Proceedings of the International Tramway and Light Railway Association* by Charles Rochat, general manager of the Geneva Electric Tramway Co., Switzerland. Of 15 rack-rail lines aggregating 67.58 miles, 9 are operated by electricity, with a total of 41.54 miles. The first was the Righi Ry., 4.24 miles, opened in 1877. The latest were the Jungfrau Ry., 5.71 miles and the Villars-Bretaye Ry., 2.29 miles, opened in 1912 and 1913 respectively. The longest is the Wengern Alp Ry., 11.78 miles, opened in 1893. Cable incline railways are 49 in number, aggregating 30.38 miles. Of these 37 lines with 24.8 miles are operated by electricity. The first was the Lausanne-Duchy line, 1.11 miles, opened in 1877, and the latest was the Trieb-Seelisberg line, only 0.7-mile, 1916. The longest of these cable inclines is the Sierra-Vermala line, 2.62 miles, opened in 1911.

News of the Week

CURRENT EVENTS IN THE CIVIL ENGINEERING AND CONTRACTING FIELDS

News Brevities

An Ordinance Zoning the city of Pittsburgh, Pa., was passed by the City Council on July 29 by a vote of 7 to 1, but at last reports awaited action by the mayor.

A Branch Line 30 Miles Long from near Forsyth, Montana south into the Rosebud County coal fields is being built by the Northern Pacific Ry. Co. to provide coal for its own use on the part of its system between Mandan, North Dakota and Missoula, Montana. A. T. Stevens is chief engineer.

Contracts for the Extension of the Toronto harbor works are in process of being awarded to Roger Miller and Co. of Toronto. The contract is for breakwater work, about 4,000 ft., in front of the exhibition grounds. The extended contract will involve a total outlay of slightly over \$1,000,000.

Authorization Has Been Given the Oregon Short Line R.R. by the Interstate Commerce Commission to build a line from Rogerson, Idaho, to Wells, Nev., a distance of 97.7 miles, on the express condition that the construction will be commenced on or before Jan. 1, 1924, and completed on or before June 30, 1925. The cost is estimated at over \$5,000,000.

Assurance That the Provincial Government would give its immediate attention to the question of the early completion of the Ottawa-Prescott highway was given by Premier G. Howard Ferguson of Ontario to a deputation which waited on him in Ottawa last week. The Prescott highway is important principally because it is an international highway giving access to the United States.

About \$20,000,000 is Being Expended and about 2,000 men are employed on work designed to enlarge and improve the grain transshipping facilities of Fort William and Port Arthur, Ont., in time for the expected bumper crops this year. The storage capacity of the two ports will be increased nearly 10,000,000 bu. by new construction, and a proportionate increase will be made in the handling capacity of the port.

Application Has Been Made by the American Niagara Railroad Corp. to the Interstate Commerce Commission for authority to construct a road from Tonawanda Junction, on the New York Central, to connect with the Canadian Niagara Bridge Co.'s line at the international boundary over the Niagara River, a total of 10.4 miles of track. This new line will furnish connections to the T. H. & B., the C. P. R., and the M. C. R.R., as a new outlet for freight from this territory which has become greatly congested.

Trenton Has Until Aug. 1, 1925, To Build Sewage-Works

The New Jersey Court of Chancery has so modified its injunction requiring the City of Trenton to stop polluting the Delaware River with sewage as to give the city until July 31, 1924, to submit plans for sewage-works and until Aug. 1, 1925, to build the works. This is a sequel to the action of the State Board of Health, on July 31, rejecting for the second time and finally plans for the direct-oxidation process and giving the city a year to file plans for treating the sewage by sedimentation. (See *Engineering News-Record*, Aug. 2, p. 198).

Rock Fill Dam for Hydro-Electric Plant in Kentucky

A rock-fill dam 800 ft. long and 270 ft. high above river bottom will be the principal engineering feature of the plant for 30,000 hp. hydro-electric development now being built on the Dix River near Lexington, Ky., by the Kentucky Hydro Electric Co., which is backed by the Middle West Utilities Co., Chicago. The head will be 235 ft. from river bed to crest of spillway section. Concrete facing will be applied to the rock fill and this in turn will be faced with timber. The dam is about 2½ miles above the mouth of the Dix River, which discharges into the Kentucky River. At present the site is being cleared, railroad spur constructed and camp buildings erected, while construction equipment is being forwarded. L. F. Harza, Chicago, is designing engineer, and the L. E. Myers Co., Chicago, has the construction contract.

Work on Parkway Tunnel in Philadelphia to Resume

The Commissioners of Fairmount Park, Philadelphia, are making plans for resumption of work on the tunnel that will carry surface cars under the Parkway in front of the Philadelphia Art Museum, work on which was stopped several months ago when funds provided for the purpose were exhausted. Resumption is made possible by the transference of about \$130,000 from the Department of Public Works to the Commissioners of Fairmount Park.

The tunnel on which work is to be started is at present simply an open cut extending across the Parkway. When completed this tunnel will carry surface cars from Spring Garden Street under the Parkway to the Spring Garden Street bridge over the Schuylkill River.

The sum set aside is not sufficient to complete the entire tunnel and put it in operation, but it will permit completion of the portion of tunnel directly crossing the Parkway, and the extension of the Parkway over this portion of the tunnel.

Irrigation District Votes \$23,000,000 Bond Issue

Verde River Project Contemplates Storage of 1,200,000 Acre-Ft. and Developing 68,000 Hp.

Special Correspondence

With but a single adverse ballot voters of the Verde River Irrigation and Power District on Aug. 7 approved the issuance of \$23,000,000 in bonds for constructing a dual irrigation and hydro-electric project, plans contemplating the storage of 1,200,000 acre-ft. of water in two reservoirs and the development of 68,000 hp. in seven power plants. The district, which will operate under the laws of Arizona, at present comprises dam sites, power sites, canal rights-of-way and 102,000 acres of irrigable land adjacent to and north of the Salt River Valley Water Users' Association—the Roosevelt project near Phoenix. The district has a right to the flood waters of the Verde River, and the amount of the normal flow not diverted by the Salt River Valley Water Users' Association. Pursuant to the action of the voters of the Verde River district bonds will be advertised for sale in the near future and construction work will be started as soon as the bonds are sold.

POWER TO CARRY FINANCING

To pay off the bonds from straight irrigation assessments would create a comparatively heavy annual bond charge for a large part of the thirty-year bond issue. In order to make the project more feasible from a financial standpoint, it is necessary to develop hydro-electric power in connection with the irrigation plans, making a dual purpose project. The two reservoirs make it possible to develop about 200,000,000 kw.-hr. per year primary power, and there is also about 20,000 additional kw.-hr. per year secondary power that can be developed by the above plants. There is sufficient market within 100 miles for all of the power and the gross revenue is estimated at \$1,900,000.

The irrigation works include the construction of either a rock-fill or a concrete constant-radius arch storage dam with a maximum height above stream bed of 265 ft. and a capacity of 950,000 acre-ft.; a multiple-arch dam with a maximum height of 160 ft. and a capacity of 240,000 acre-ft.; a concrete arch diversion dam with a height of 28 ft.; canals of a total length of 62 miles; a small earth-fill dam; a distribution system for 102,000 acres.

Power will be developed in seven plants, according to the following distribution: 24,000 hp. operating under maximum head of 265 ft.; 3,700 hp. with maximum head of 90 ft.; 12,000 hp. with head of 292 ft.; 3,000 hp. with head of 190 ft.; 6,800 hp. with head of 145 ft.; 8,700 hp. with head of 175 ft.; and 4,900 hp. with head of 95 ft.

The directors of the district are E. W. Michael, president, and J. D. Bowers and H. C. Ludden. John G. Bailhache is chief engineer for the district.

Bluff Plan for Arkansas River Control Approved

District Judge Park Finds Official Project for Flood Control at Pueblo Most Adequate

Formal approval has been given the bluff plan for controlling the flood waters of the Arkansas River at Pueblo, Colo., by District Judge Park, after hearings that lasted more than a week and after careful consideration of all controversial points and the examination of four other plans designed to avert repetition of the disastrous flood of 1921. In accordance with the court's decision construction work will start as soon as sale of the conservancy district bonds can be arranged. (For full description of the bluff plan see *Engineering News-Record*, July 12, p. 48.)

THREE OBJECTIONS MADE

Three principal objections had been raised to the execution of the bluff plan; that it offered excessive protection; that it entailed expense out of proportion to the ability of the city and district to pay; and that it endangered the intake and distribution system of the South Side Water Board.

To the first of these objections Judge Park asserted that, though provision for the control of 115,000 sec.-ft. (25,000 sec.-ft. more than the peak flow during the 1921 flood) might be sufficient protection, he believed that the greatest reasonable protection, even though considered popularly excessive, should be provided. The bluff plan contemplates control of a flood of 180,000 sec.-ft., not an impossible flow as testified to at the hearing by flood-protection consultants.

On the proposition of expense Judge Park said that by far the greatest number of objections of increased taxation because of the improvement had been registered by property owners outside of the conservation district. An appraisal of cost given was that the bluff plan would increase taxes but \$3.84 per \$1,000 of valuation outside the district as against \$2 per \$1,000 valuation for the cheapest of the other four plans submitted. As \$4,000,000 had been made as a high estimate and as a liberal sum was included therein for engineering, contingencies and the acquisition of property over which the new channel would flow, the actual construction could be done, it was estimated, at considerably under \$3,000,000, a sum deemed not excessive by the court.

WATER-BOARD ISSUE

Judge Park said that the objections of the South Side Water Board that its intake would be endangered could be raised against any of the plans and therefore was not to be taken as a too serious objection. That matter was something to be adjusted between the district commission and the water board, said Judge Park.

Opposition to the two other chief plans for controlling the Arkansas was registered by Judge Park principally on the ground that were greater floods to occur than 115,000 sec.-ft., Pueblo would have no protection.

Preliminary investigations and surveys for the project were begun in September, 1921, by the Dayton Morgan Engineering Co.

Moffat Tunnel Bid Opening Postponed Three Weeks

In order that contractors may have more time in which to study plans and specifications, bids for the construction of the Moffat Tunnel through the Colorado Rockies are not to be opened until Sept. 16 according to an announcement by W. P. Robinson, chairman of the commission. The original date was set for Aug. 25.

Southern Pacific to Build Natron Cutoff

Following the announcement that the United States Government will not appeal the recent decision against it in the suit for the dissolution of the merged Southern Pacific and the Union Pacific, the chairman of the executive committee of the Southern Pacific has announced that the railroad company will proceed at once to complete the Natron cutoff. Work on the cutoff was stopped in 1912 when the dissolution suit was started. There still remain 118 miles to be constructed, from Oak Ridge, Ore., over the Cascade Mountains to Kirk, Ore. Survey parties are now at work on this line, which will not only open up a fertile section of country but will also give the Southern Pacific a second line parallel to the coast with much better grades than there are on its present line. The total cost of the work will be between \$10,000,000 and \$12,000,000.

Illinois Society Acts in Case of A. P. Davis

After consideration of the recent dismissal of A. P. Davis as Director of the U. S. Reclamation Service, the Illinois Society of Engineers has passed the following resolutions:

"Resolved, That in regard to the recent summary dismissal of A. P.

Davis, a highly competent and experienced engineer and executive, from the position of Director of the U. S. Reclamation Service, the Illinois Society of Engineers makes emphatic protest against this action of the Secretary of the Interior and against the unjust and sinister method in which this dismissal was effected, namely, by abolishing the position, thus leaving the Director without opportunity for redress.

"Furthermore, protest is made against the appointment of a local banker to practically the same position, but under another title created for the purpose.

"Resolved, That the position in question is one requiring both technical skill and administrative ability, both of which have been exercised by Mr. Davis for several years with marked benefit to the Reclamation Service, the public, and the development of the arid region. And such political interference with work of such importance is a serious detriment to the public welfare, to the work of the Reclamation Service and to the civil service principle, as well as to the engineering profession!"

California A. G. C. Protests Bidding Up Wages

At a special meeting of the Executive Board called for the purpose of dealing with the objectionable practice of contractors bidding up wages for building craftsmen during periods of apparent shortage of help, the Southern California Chapter of the Associated General Contractors of America adopted a resolution against this practice. This resolution, which has been sent to employers in the building construction industry, calls upon the builders and contractors of Southern California to put an immediate end to the practice of recruiting crews of skilled workers from other jobs by offering to pay more than the prevailing wages. The resolution calls attention to the hardship caused to the builders so deprived and the restriction of output of local workmen because of lost time in turnover and the removal of incentive for honest effort.

Break in 24-in. Water Main at Seattle, Wash.

PAVEMENT BROKEN BY BURST WATER MAIN AT SEATTLE

A break in a low-service water main at Seattle, Wash., July 20, broke up pavement, as shown in the accompanying view, flooded basements and dam-

aged property to the estimated amount of \$50,000. Gates only a block distant in either direction made the stoppage of the flooding easy.

Sacramento Municipal Utility District Created

By a popular vote of 6,378 to 978 out of a total registration of about 36,000 a municipal water and power development scheme for the benefit of Sacramento, Calif., and presumably some adjoining territory, was authorized on July 2. The proposal voted on was the creation of the Sacramento Municipal Utility District, and the election of five directors of the district. The project on which engineers have already made a preliminary report is for the development of a maximum of 150,000 hp. from the waters of Silver Creek, a tributary of the American River, together with the purchase of the distribution systems of the Great Western Power Co. and the Pacific Gas & Electric Co. within the newly created district. Condemnation proceedings for acquiring these distribution systems are proposed. The estimated cost of the entire project is \$8,000,000, divided equally between the new power development project and the acquisition of the distribution system named. An election to vote on bonds for the project is proposed for this fall.

The storage system includes two main reservoirs with a total ultimate impounding capacity of 210,000 acre-ft. and a tributary drainage area of 191 sq.mi. One of the two main reservoirs would be at Union Valley on the main fork of Silver Creek and would be formed by a dam 302 ft. high. The other main reservoir would be at Ice House on the south fork of Silver Creek and would be formed by a dam 138 ft. high. H. C. Bottorff is city manager of Sacramento.

F. A. E. S. Active in Pushing Coal Storage Investigation

Pursuant to its investigation into storage of coal, in co-operation with that of the United States Coal Commission, the Federated American Engineering Societies has sent out a questionnaire to local storage of coal committees of the various engineering organizations, and to their sub-committees, to be by them distributed to the industries.

Printed outlines and sheets giving classifications of industries to be covered are being sent to the chairmen of local storage of coal committees. Upon receipt of these, the chairmen are requested to call meetings of their committees, select the most important consumers of coal in their city and its vicinity, then distribute the questionnaire to the official of each company who will be best able to supply the information desired. Request is made that the classification of industries be followed and that as many companies as possible under each classification be covered, but at least one under each group.

The local committees are at liberty to develop plans as extensively as possible, securing the co-operation of local civic organizations, trade associations or individuals. The Storage of Coal Committee of the F. A. E. S. will handle from the executive office in Washington the largest corporations which have affiliations and branches in many cities, especially the steam railways, steel mills, meat packing houses, sugar refineries, dock and pier storage companies and the navy and merchant marine.

Developing More Water Power in Minnesota

To meet the rapidly increasing power demands of the Mesabi and Vermilion coal ranges of Minnesota a number of electric developments are under way. The Phoenix Utility Co. is increasing its capacity by 40,000 hp. at an estimated expenditure of \$7,000,000. The Kawishiwi hydro-electric development of the Minnesota Utilities at Ely, Minn., is nearing completion. It will have an output of 12,000 hp. which will be transmitted 52 miles to the iron mines at Virginia at a voltage of 110,000. The Great Northern Power Co. is also constructing a 110,000-v. line from its Thompson plant to the western end of the Mesabi range. In addition to these developments a 30,000-hp. hydro-electric plant has been started on the St. Louis River just above Fond-du-lac, Minn. This project involves the construction of a concrete dam 100 ft. high and 650 ft. long. Eighteen-foot penstocks will serve the two 15,000-hp. generators.

Cannot Zone Against Two-Family Houses in New Jersey

Direct prohibition of two-family houses is not permissible under the New Jersey statute authorizing municipalities to enact zoning ordinances, declares Chief Justice Gummere in a Supreme Court decision filed on July 31. The suit was brought by the owner of a three-story brick building in Westfield, who had been denied a certificate of occupancy for two families. The judge held that zoning ordinances in New Jersey are based on the promotion of the public health, safety and welfare, and that:

"The [Westfield] ordinance operates upon every residence within the prescribed district, without regard to its size, sanitary appliances or convenience. It permits occupancy and

High Speed Motorway for Britain

An innovation in British highway improvement schemes is the proposal to construct a high-speed road from London to Birmingham, about 100 miles. This project will be taken in hand by private enterprise, with the approval of the Ministry of Transport. The route is through Aylesbury, Banbury, Leamington and Coventry. The road will be surfaced with concrete and will be 50 ft. wide and is estimated to cost about six-and-a-half millions sterling, including land, buildings and bridges.

Only mechanically-propelled vehicles will be permitted and pedestrians will be prohibited. Each vehicle will be subject to a toll on tonnage, from which the revenue will be derived. It is estimated that a saving of 20 to 35 per cent on transport charges will be effected. Public passenger cars will run at scheduled times at speeds of 30 to 50 m.p.h. stopping only at the main towns. If the project is a success the road will be extended to Manchester.

Wateree River and Swamp Crossing Is Completed

On July 22 the completion of the Wateree River bridge, on the main highway between Columbia and Sumter, S. C., was celebrated by a large opening ceremony held at Statesburg. The bridge, 4½ miles long with its approaches through the swamps of the Wateree, is one of a group of four large river crossings now under construction in South Carolina to provide intercommunication in the coastal plain section of the state, as outlined by J. L. Parker, bridge engineer of the state highway department, in *Engineering News-Record* of Nov. 3, 1921, p. 725. Hitherto the main rivers of the state have not been crossed by a bridge within 170 miles of the sea, and ferries have been the only means of communication; the program now in

RIVER CROSSING AND CONCRETE TRESTLE OF WATeree BRIDGE

use of a residence by a single family, no matter how large, but prohibits occupancy by two families, although the total membership of the two may be much less than that of the one.

"In short, its only purpose, so far as can be discovered from the language used, is to place a restriction upon the use of residential properties within the designated area without any pretense that such restriction is reasonably necessary for the public health and safety."

course of execution is the beginning of the work of correcting this condition.

The Wateree bridge with approaches cost about \$300,000, of which half was expended on the main structure. This is slightly over 2,000 ft. long, and comprises two 165-ft. steel spans, 25 spans of concrete trestle of 36½ ft. each, and 49 spans of cross-tied timber trestle of 16 ft. each. It was built by the Hardaway Construction Co., of Columbus, Ga., and the Austin Bros. Bridge Co., of Atlanta, Ga.

How To Become a Consulting Engineer

Sir:—You and your lynx-eyed correspondents have uncovered some decidedly rare specimens of specialized engineers. A much older member of this family is the self-styled "Consulting Engineer" of a certain type. How they "get that way" has long been a source of wonderment to the writer.

Perhaps the answer, in part, at least, may be found in the enclosed advertisement which was clipped from the *Help Wanted* columns of the Aug. 8 issue of the *New York Times*.

ELECTRICAL ENGINEER, who has had considerable experience in transformer design to tutor an engineer about to engage in consulting work in the fundamentals and practical design; evenings preferred; state experience, location and rate. C 400 Times.

The advertiser, an embryonic "Consulting Engineer," in this instance, at least, is apparently endeavoring to become prepared in the fundamentals of his chosen field before he essays to advise the rest of the profession. Let that much be recorded to his credit. For it is much more than can be said of quite a few of his brethren.

A. E. C.

* * *

Up in Buffalo, Karr Parker has been elected president of the local engineering society. Under the inspiration of such a name the Buffalo society should get something done about the automobile congestion in the downtown district.

In Explanation

A correspondent has submitted an advertisement of a "belting engineer" to be added to our *index ridiculous* of adjectival engineers. This prompts a brief explanation. There are many adjectives quite properly applied to the word engineer to describe a specialty. The test of propriety would seem to be the qualification of the person so described to the term engineer, unmodified and alone, and the justification of the specialty to be a branch of engineering. Thus our much advertised friends the "exterminating engineers" are jokes, because the gentlemen who engage in this useful business are not, when so engaged, engineers, nor is the removal of bugs from kitchens a branch of engineering. So too our "hymn book engineers," and a newcomer, a "kitchen engineers" who helps a Buffalo supply house sell cook stoves and steam tables, are only stealing an honorable title. On the other hand when you come to "belting engineers" the case is not so clear. The proper solution of the problems of belt design and application may call for engineering skill and there may reasonably be engineers whose entire professional practice is confined to so narrow a field. There may be criticism for such close delimiting of professional activities, but it is all in the family. The jibes at "insurance engineers," who are merely insurance salesmen and "merchant engineers" who are heaven knows what, are expressions of group resentment. The more publicity that can be given to such resentment the sooner will the practice of title stealing be stopped.

Six Scalded to Death When Bus Rams Concrete Mixer

Six women died from burns and shock received last week when the autobus in which they were returning to New York City from an outing rammied a concrete mixer, near Nyack, ripping away the main steam supply line from the boiler to the mixer. The accident happened on Highland Avenue, where a state road is under reconstruction. The road is being rebuilt half width at a time. Two buses composed the party; and the first of these had succeeded in passing the mixer on the narrow strip, but the second side-swiped it, then became so entangled in the wreckage that the bus driver was unable to proceed. The broken steam line enveloped the occupants of the bus, who were all employees of the *Christian Herald*, New York City, with steam, with the fatal results noted.

Though the accident happened in the evening after the road gang had quit for the day, it is said that the mixer boiler showed a steam pressure of 150 lb. When the line was broken, the mixer tender could do nothing to shut the steam off. The road at the point of the accident is being reconstructed under state supervision.

An investigation is under way to determine the exact cause of accident and to fix responsibility for its fatal results.

New Hudson River Connecting R.R. Will Have No Grade Crossings

In anticipation of any future need of grade crossing separation, the Hudson River Connecting R.R. Co., which is building the Castleton cut-off on the New York Central System, will provide over or under crossing for all of the seventeen highways on its new line. For this purpose it has presented five petitions to the Public Service Commission at Albany. Physical conditions determine the type of crossing used at the various points. The plans filed call for an overhead bridge at Courtney crossing in Stuyvesant, an under pass at McCabe's in Stuyvesant, and under passes for the Reguas highway and the county highway in Columbia County. The two latter highways are to be reconstructed by the railroad on a new alignment.

City-Manager Plan Voted Down at Plainfield, N. J.

The commission-manager plan of city government has been rejected by the voters of Plainfield, N. J., 2,225 to 346. The total vote was only 40 per cent of that at the last gubernatorial election and the vote for the plan was less than half the number of signers of the petition. The election was held under a law passed last winter—the first authorization of the manager plan in New Jersey. The plan was also defeated recently by the voters of Deal, the first municipality in New Jersey to vote on it. Plainfield is operating under the mayor-and-council plan, and is one of a few cities or towns of size in the state which has not adopted the commission as contrasted with a commission-manager plan.

Coolidge Withholds Policy on Anthracite Question

While officially there has been no move made by the federal government in the anthracite situation, it is known that the threatened cessation of work in the hard coal fields when the present agreement expires Aug. 31 has been given considerable thought by President Coolidge as well as by other officials. Despite many rumors and newspaper reports asserting as a fact that first one course then another will be pursued by the government, there has been no formal announcement of policy.

The activities of the Coal Commission have been restricted in the last week owing to the halting of governmental activities in Washington for three and a half days on account of the death of President Harding. Members of the commission have been watching for developments in the anthracite situation but formal meetings of the body practically were suspended for a week.

The Coal Commission made public last Wednesday a report submitted it by a special staff composed of Henry S. Dennison, Willard E. Hotchkiss and Joseph H. Willits, on "Labor Relations in the Anthracite Industry." This report was one of those upon which the commission based its recent report and recommendations regarding the anthracite industry.

The commission also made public a statement showing that it will be impossible for the commission to make the detailed investigation of the retail coal industry throughout the country as such a survey would cost \$2,000,000 and in all probability would not be conclusive.

As the crisis in the anthracite industry through the apparent deadlock in negotiations between operators and miners is of immediate importance and is pressing for attention as the days of August pass, the situation has been called to the attention of President Coolidge by a number of visitors who were accorded audience with him in his first week as Chief Executive. It may be stated upon reliable authority that President Coolidge has not indicated a course of action definitely.

Newfoundland to Develop Power and Build Paper Plant

The Newfoundland legislature, on July 11, approved the agreement whereby the government will take over the Newfoundland Railway from the Reid-Newfoundland Co., along with land and port facilities belonging to that company. It also confirmed the agreement whereby the Newfoundland Power & Paper Co. is to develop hydroelectric power and establish a paper mill on the Humber River.

The company is to issue \$20,000,000 worth of bonds, one-half of which is to be guaranteed by the British government, to be expended in Great Britain for machinery and other equipment; the other half is to be spent in acquisition of lands and buildings in Newfoundland.

The contract for the excavation of the canal on the Humber River, as the first step in this development, has been awarded to the Northern Construction Co. of Vancouver, B. C.

Engineering Societies

Calendar

Annual Meetings

- NEW ENGLAND WATER WORKS ASSOCIATION, Boston, Mass.; Annual Convention, Burlington, Vt., Sept. 18-21, 1923.
- INTERNATIONAL ASSOCIATION OF STREET SANITATION OFFICIALS, Chicago, Ill.; Annual Conference, Chicago, Sept. 27-28, 1923.
- AMERICAN PUBLIC HEALTH ASSOCIATION, New York; Annual Meeting, Boston, Oct. 8-11.
- AMERICAN SOCIETY OF CIVIL ENGINEERS, New York; Fall Meeting, Richmond, Va., Oct. 17-20.
- AMERICAN SOCIETY FOR MUNICIPAL IMPROVEMENTS, St. Petersburg, Fla.; Annual Convention, Atlanta, Ga.; Nov. 12 to 16.

The North Carolina Society of Engineers held its annual convention August 10 and 11 at Asheville, N. C., and the North Carolina Branch of the American Association of Engineers held its sessions at the same time. John L. Becton is president and H. K. Witherpoon is secretary-treasurer of the first-named society.

The New York Chapter of the American Association of Engineers has elected the following officers: E. G. Haines, president; Dr. D. B. Steinman and Walter E. Brown, vice-presidents; Paul S. L. Bolger, treasurer, and Walter A. Craft, secretary.

The Duluth Engineers Club recently elected Frank Hutchinson president for the coming year. A. U. Shipman is the retiring president. Other officers elected are: Arthur M. Frazee, first vice-president; H. W. Richardson, secretary; Fred C. Baluss, treasurer; and F. E. House, J. L. Pickles, W. A. Clark and A. U. Shipman, directors.

Personal Notes

J. M. MARSHALL has been appointed district engineer of the Portland Cement Association office at Atlanta, Ga., succeeding WALTER B. ELCOCK, who has recently been promoted to assistant general manager in charge of the southeastern offices of the association. Mr. Marshall is a graduate of the Virginia Military Institute. To 1917 he was engaged in engineering work for the Seaboard Air Line and Pennsylvania R.R., and in rapid transit subway construction in New York City. He was a captain in the 11th Engineers and since the war has been connected with the New York office of the Portland Cement Association.

JAY T. WILLIAMS, civil engineer of Denver, Colo., and for the past seven years connected with the C. S. Lambie Construction Co., has been appointed building inspector for the city of Denver, succeeding FRANK M. LADD, retired by the newly elected mayor.

COMMANDER C. A. CARLSON, U. S. N., has been detached from duty as public works officer of the 14th Naval District at Pearl Harbor, Hawaii, and has been assigned to succeed CAPTAIN L. M. COX, U. S. N., the public works officer at Mare Island, Calif. Captain Cox has been on duty since 1919 and will be retired at his own request.

HARRY A. STORRES of San Francisco has been appointed chief engineer for the Modesto Irrigation District at Modesto, Calif., succeeding Percy F. Jones, resigned.

MYRON HENDEE, formerly connected with Thomas F. Bowe, consulting engineer, New York City, has taken up practice in surveying and municipal engineering in Bogota, N. J.

RUDOLPH P. MILLER, consulting engineer of New York City, the representative of American Engineering Council on the National Board for Jurisdictional Awards in the Building Industry, was elected chairman of that board at its recent meeting in Atlantic City, N. J.

STAFFORD X. COMBER announces resumption of private practice as consulting engineer in public works and general construction in the domestic and foreign fields. Mr. Comber, who is an American, educated at the University of London, was in 1918 retained by the British government to report on water resources in British Guiana, and also built reinforced-concrete drainage and irrigation works at Demerara. Later for a European contracting firm he visited the Mourne Mountains, Ireland, and reported on a large dam construction for the city of Belfast. Again for the British government he reported on a route for a mountain highway and hydro-electric railway to the interior of Venezuela and Brazil. Mr. Comber's earlier work was with contractors in New York City, on Pennsylvania R.R. tunnels, on work for the Ashokan Dam and the Catskill Aqueduct, on subway construction and underpinning of large city buildings. For a short time he was production superintendent of ten factories in France and Belgium breaking down surplus Allied and surrendered German ammunition and recovering metal and chemicals for commercial use; also he was for a time progress engineer for the Southern California Edison Co. His present address as consulting engineer is 32 West 40th St., New York City.

LOUIS E. AYRES, GEORGE E. LEWIS, ROBERT NORRIS and DONALD C. MAY, Ann Arbor, Mich., announce the formation of a partnership for the practice of hydraulic and electrical engineering. All of these men have been with GARDNER S. WILLIAMS, consulting engineer; Mr. Ayres as principal assistant engineer, Mr. Lewis as electrical engineer, Mr. Norris as supervising engineer and Mr. May as designing engineer. Mr. Williams will continue his consulting practice at his old address.

W. EARL WELLER, city engineer of Binghamton, N. Y., has accepted a position in the Bureau of Municipal Research, Rochester, N. Y., to compile data on municipal projects in all sections of the country of interest to the city of Rochester. Mr. Weller designed the boulevard lighting systems of Binghamton, established a new accounting and tax assessment system

for the city, and also designed the memorial bridge across the Chenango River. Mr. Weller has not definitely decided when he will leave Binghamton.

NORMAN L. STANN, chief engineer of the Department of Wharves, Docks and Ferries, Philadelphia, Pa., and for 27 years in municipal service in Philadelphia, having been made assistant engineer of the Bureau of Surveys in 1897, has retired, on the pension list.

JOSEPH A. ELLIOTT has been appointed superintendent for the Utah Construction Co. on the construction of a new line of the Southern Pacific in Mexico between Tepic and Guadalajara. Mr. Elliott has recently been in charge of the construction of an icing plant in Nevada for the Western Pacific Ry.

C. E. BLEE, formerly assistant engineer, California-Oregon Power Co., Medford, Ore., has accepted a position at Vancouver, B. C., as chief assistant to E. E. Carpenter, consulting engineer in charge of new construction for the British Columbia Electric Co. Mr. Blee has been associated with Mr. Carpenter on three previous construction jobs, the Jordan River power development and the Sooke water project on Vancouver Island, and in the construction of buildings for the Panama-Pacific International Exposition.

IRVING R. FRAY has severed his connection with the Louisiana Highway Commission, engineering department, where he has served since the organization of the commission, and has been made special representative of the Southern Surety Co. of Des Moines, Ia., with headquarters at Baton Rouge, La.

Obituary

LEROY W. CUMMINGS, a highway engineer in the employ of the California Highway Commission, died near Clear Lake, Calif., recently at the age of 43 years. Mr. Cummings was a graduate of Harvard University. Prior to the World War he was a construction engineer for the California Highway Commission. He served during the war as a captain of the 23rd Engineers and then became senior highway engineer with the Bureau of Public Roads stationed at Chicago. Later he rejoined the military establishment as captain of engineers but resigned on account of poor health and in the spring of 1923 again entered the service of the California Highway Commission.

THEODORE RALL, chief engineer of the Strobel Steel Construction Co., died recently in Chicago. He was the inventor of the Rall type of bascule bridge.

HERMANN J. STROBEL, supervisor of appraisals, of Stone & Webster, Inc., Boston, died Aug. 3 following an operation. He was 41 years old and had been with the Stone & Webster organization for the past eleven years in electrical engineering and appraisal work. From 1905 to 1911 he was with the New York Central & Hudson River Railroad in New York as chief draftsman and assistant engineer on the electrical work of the Port Morris and Yonkers power stations and the Grand Central Terminal.

Construction Equipment and Materials

Steel Corporation Starts Abolition of 12-Hr. Day

Change to Eight Hours to Be Gradual—
Workers to Get Higher Pay Rate
But Will Earn Less

In accordance with a decision arrived at more than a week ago by the American Iron and Steel Institute, confirmation of which intent was given later by Judge Elbert H. Gary, abolition of the 12-hour day in the steel industry begins today, Aug. 16. This action is the culmination of a series of conferences which began late in June after President Harding had asked the Institute to guarantee ending the long steel day as soon as labor conditions in the industry would permit. Elimination of the 12-hour shift and the 24-hour shift once every two weeks will progress as rapidly as the supply of labor will permit. It will not, however, be simultaneous in all of the Corporation plants, changes depending upon labor conditions in the respective mills.

JUDGE GARY'S STATEMENT

According to Judge Gary's statement of ten days ago "where the hours of employees connected with continuous process are reduced from 12 to eight hours, their wage rates will be so adjusted as to afford earnings equivalent to a 25 per cent increase in hourly and base rates. All other workmen will be on 10 hours or less and their present hourly and base rates will be continued; but whenever it is practicable, by promotions or changes in position, the daily earnings will be accordingly adjusted."

It has been estimated that 60,000 more men will be needed in the steel mills to make possible the total elimination of the 12-hr day. It is understood that about 60 per cent of the quarter million employees of the Corporation are working on the two-shift basis of 12 hours each. The hourly rate of these workers is 40 cents. The daily wage would therefore be \$4.80. Should the hour rate increase 25 per cent, that would mean a base pay of 50 cents, and on an eight-hour shift a daily rate of \$4. In wages therefore 80 cents a day will be lost but four hours more leisure will be gained for the workers.

EFFECT ON PRICES

What effect the elimination of the 12-hour day will have on the price of steel products is problematical, but when a change to eight hours was first considered the Institute received a report from an investigating committee that prices would be raised about 15 per cent by the change. Installation of mechanical devices and removal of certain immigration restrictions to allow the absorption of a greater number of alien workers should, it was believed, offset this theoretical price advance.

Oil Equipment Manufacturers To Hold Exposition at Tulsa

With 125 manufacturers of oil equipment and appliances signed up as exhibitors at the International Petroleum Exposition and Congress, to be held in Tulsa, October 8-14, the directors of the "first world oil show" declare the display of machinery, scientific instruments, mechanical equipment and new devices, all of interest in some phase of the oil industry, will be one of the largest exhibitions held in that part of the country. Every phase of the oil business will have its technical display. Supply companies, belt and cordage makers, rig manufacturers, tank and pipe makers, will all present displays—for oil producers. Displays also will attract the refiner, the jobber, marketer and filling station man.

Tulsa's convention hall will be the center of activity during the exposition. Streets on all sides of this building will be closed and fair buildings are to be erected for housing the displays.

New July Record Set for Automobile Production

Production of motor vehicles in July was 318,000, according to the estimates based on shipping reports received by the National Automobile Chamber of Commerce. As expected, July showed a slight seasonal decline, compared with the extraordinarily large records of the previous months; but compared with the corresponding month in previous years July set a new record, gaining 29 per cent over July 1922. The weekly trend in production was upward during July, the last two weeks being larger than the first two weeks in the month. The output of cars and trucks during the first seven months of this year was 2,344,000, showing an increase of 68 per cent over the corresponding period last year.

Number of Locomotives Needing Heavy Repair Increases

According to a recent statement issued by the Car Service Division of the American Railway Association, Class One railroads of the United States had in need of repair on July 15, 11,855 locomotives, or 18.6 per cent of the total number on line. This was an increase of 405 over the total number on July 1, at which time there were 11,450. Of the total number on July 15 last 10,784, or 16.9 per cent, were in need of heavy repair. This was an increase of 458 over the number in need of such repair on July 1.

The railroads on July 15 had 2,437 locomotives in good repair and stored away to meet increased traffic demands later in the year. This was an increase of 256 over the number in storage on July 1.

During the first fifteen days in July 18,290 locomotives were repaired and turned out of the shops.

Preliminary Plans Made for 1924 Road Show

Record Convention and Greatest Number of Exhibitors Forecast —
Questionnaire Circulated

From interest manifested by exhibitors and state highway officials, the 1924 convention of the American Road Builders' Association will be greater than any previous one, according to Charles Upham, convention manager and state highway engineer of North Carolina. Already preliminary plans for the convention and the Road Show have been made and certain blanket contracts entered into for moving machinery to the Coliseum in Chicago where the Show is to be held.

Mr. Upham, in a recent bulletin, asserts that the indications point to an early rush for space and that while every attempt will be made to locate satisfactorily all exhibitors, it is already apparent exhibitors will not be able to get as much space as they desire, nor will location in every instance be ideal. However, with the idea in mind to locate every exhibitor as agreeably as possible, a questionnaire has been circulated among manufacturers requesting information as to satisfaction of location and amount of space at the 1923 convention, value of registration of delegates to the convention, the comparative value from an exhibit standpoint of various exhibit locations.

ROAD SHOW DATES

The Road Show is to be held from January 14 to January 19. The Coliseum will be occupied until 12 o'clock on Jan. 12. However, exhibitors are to be allowed to store their equipment up to five days ahead of this time in the annex. Exhibits in the ballroom may be set up Jan. 7. The main floor of the Coliseum will not be available until Jan. 13 and the balcony until Monday, Jan. 14. This condition will exist because a show is to be held in the Coliseum during the week previous to the American Road Builders' Show. Negotiations are now under way with the Coliseum people to change the time of the show that is to be held previous to the Road Show, so that additional time may be secured. Definite arrangements on this score are to be concluded before Aug. 20. The Greer Building will be available to exhibitors five days previous to the opening of the Road Show.

The Congress Hotel has been selected as convention headquarters where the daily meetings and the annual banquet will be held. The organization for handling the Road Show in 1924 will be somewhat similar to that which functioned this last January.

Engines Exported

Exports of stationary internal combustion engines during May, according to figures from the Department of Commerce, were as follows: 359 Diesel and semi-Diesel engines valued at \$130,976; 2,968 gas engines not over 8 hp. valued at \$255,265; and 113 gas engines over 8 hp. valued at \$72,251.

Argentina received the greatest number of the Diesel engines, 310, costing \$117,800. Japan was the biggest user of the gas engines under 8 hp., taking 1,225, costing \$100,220.

Government Figures on Industrial and Commercial Movements

The Department of Commerce announces the following figures representing industrial and commercial movements in June:

Contracts awarded for construction in 27 northeastern states amounted to \$323,559,000 in June as against \$374,400,000 in May and \$343,440,000 in June a year ago. In point of floor space construction contracts awarded in June aggregated 46,344,000 sq. ft. as against 60,430,000 sq. ft. in May and 60,526,000 sq. ft. in June, 1922.

Production of Southern pine lumber amounted to 450,408,000 board feet as compared with 499,247,000 ft. in June a year ago. Stock on hand at the end of June aggregated 1,054,133,000 ft. as compared with 1,095,580,000 ft. on June 30, 1922.

Production of oak flooring in June amounted to 34,342,000 board feet as against 34,636,000 ft. in May and 23,495,000 ft. in June a year ago. New orders booked called for 15,081,000 ft. as against 22,677,000 ft. in May and 24,472,000 ft. in June, 1922.

Production of clay fire brick in June amounted to 63,861,000 bricks as against 48,367,000 bricks a year ago. New orders amounted to 46,244,000 bricks as against 57,805,000 bricks ordered in June, 1922.

Total of 24,640,000 face brick was produced in June as compared with 26,057,000 in May and 28,673,000 in June a year ago. Unfilled orders at the end of June amounted to 54,128,000 bricks as against 57,363,000 bricks on May 31 and 43,283,000 on June 30, 1922.

Brick Paving Committee Conference Postponed

Due to the inability of two of its members to attend the meeting scheduled for Tuesday, Aug. 14, the session of the Advisory Committee of the National Paving Brick Manufacturers Association has been postponed until the following Tuesday, Aug. 21, at Cleveland. This meeting is primarily to consider and take action on the revised specifications and text book on Brick Pavements.

The invitation extended to the membership of the association to submit suggestions as well as to attend this meeting in person still holds good.

Steel Industries Plan Exposition

Over 100 manufacturers of steel mill apparatus have combined to hold an iron and steel exposition at the Buffalo, N. Y., auditorium, Sept. 24-28. Exposition managers plan to make the demonstration one of the greatest exhibitions of electrical, mechanical, power and combustion apparatus. One of the features of the exposition will be a modern electrified foundry which will be in actual operation under the supervision of E. T. Langworthy, a steel expert. The foundry will produce finished products and will start with hot metal, passing from machine to machine until its final form.

The purpose of the exposition is chiefly to bring to the attention of the steel mill world the latest improvements in devices which have to do with the conservation of fuel, production of steel, etc.

Gypsum Production for 1922 Nearly 4,000,000 Tons

According to a statement issued by the Department of the Interior, compiled from statistics collected by the U. S. Geological Survey, the demand for most of the gypsum products was greater in 1922 than in 1921. During the year 3,779,949 tons of gypsum were mined, an increase of 24 per cent over the output in 1921. The sales of agri-

GYPSUM PRODUCED AND SOLD IN THE UNITED STATES IN 1922, BY USES

Calculated:	Short Tons	Value
Suoco.....	396,990	\$2,813,561
Neat plaster.....	1,332,261	12,126,811
Sanded plaster.....	80,455	1,163,771
Mixed plaster..... (a)	218,650	1,914,572
Plaster of Paris, molding, casting plaster, etc..... (b)	126,268	1,198,819
Plaster board.....	21,991	324,516
Wall board.....	42,088	945,171
Partition tile.....	120,591	4,500,725

Special tile or blocks.....	44,834	368,068
Other purposes.....	37,779	644,542
Crude.....	2,491,265	\$26,917,805
	770,725	2,443,346
		\$29,361,151

(a) Includes small quantity of wood fiber plaster.
(b) Includes dental plaster and plaster sold to pharmaceutical works. (c) Included under "Other purposes."

cultural gypsum decreased from 104,966 tons, valued at \$490,902, in 1921, to 101,904 tons, valued at \$387,203, in 1922. The sales of gypsum for use in Portland cement, paint, and other compounds amounted to 668,821 tons, valued at \$2,056,143, an increase over the corresponding figure for 1921 of 24 per cent in quantity and of 16 per cent in value.

The accompanying table shows by uses the quantity and value of gypsum sold during 1922. Much of the difference between the 3,779,949 tons of gypsum mined and the 3,261,590 tons produced and sold in United States represents exports.

Compton to Study Lumber Conditions Abroad

Wilson Compton, secretary-manager of the National Lumber Manufacturers Association, is now in Europe and will represent the American lumber industry at the Swedish Tri-Centennial Exposition at Gothenburg. The Bureau of Foreign and Domestic Commerce of the U. S. Department of Commerce has requested A. X. Oxholm, chief of the lumber division, who is already in Europe, to accompany Mr. Compton on his special tour of the Swedish saw mills and forests. Mr. Compton's special purpose in the Swedish trip is to get a first hand impression of waste prevention and raw material utilization methods of Scandinavian mills.

The United States commercial attaches in different European cities will assist Mr. Compton in his study of the methods used in Europe for enforcing and guaranteeing lumber quality and dimension standards. Mr. Compton will also probably make a brief tour of German national and municipal forests, in company with a party of Oxford foresters under the guidance of Dr. C. A. Schenck, of Darmstadt, who was formerly in charge of the Biltmore Forest School in North Carolina.

West Coast Lumber Production 17 Per Cent Above Normal

One hundred and thirty mills reporting to the West Coast Lumbermen's Association for the week ending July 28, manufactured 103,264,839 ft. b.m. of lumber; sold 95,063,633 ft.; and shipped 97,842,724 ft. Production for reporting mills was 17 per cent above normal. New business was 8 per cent below production. Shipments were 3 per cent above new business.

Thirty-nine per cent of all new business taken during the week was for future water delivery. This amounted to 36,669,991 ft., of which 26,530,805 ft. was for domestic cargo delivery; and 10,139,186 ft. export. New business by rail amounted to 1,792 cars. Thirty-nine per cent of the week's lumber shipments moved by water.

In the first thirty weeks of the year, production reported to the West Coast Lumbermen's Association has been 2,941,715,476 ft.; new business 3,027,109,400 ft.; and shipments 3,210,996,676 ft.

Business Notes

RAYMOND CONCRETE PILE Co. announces the opening of a Pacific Coast office in the Washington Bldg., Los Angeles, Calif., with O. C. Struthers, formerly with Pratt & Thompson, Kansas City, in charge.

JOHNSON GAS APPLIANCE Co., Cedar Rapids, Iowa, manufacturers of gas torches and furnaces and other appliances, have taken over the manufacture and sale of the Moore self-cleaning rake, having acquired on July 1 all equipment, stock, patent rights, etc., of the Moore Self-Cleaning Rake Co. of Cedar Rapids.

SOUTHERN PINE ASSOCIATION at a recent meeting in Chicago elected H. C. Berckes, of New Orleans, secretary-manager to succeed the late J. E. Rhodes, who died recently. Mr. Berckes has been connected with the Southern Pine Association staff almost since its organization in 1915 and has been assistant secretary since 1919.

GILMORE OIL Co., Los Angeles, is the name of the new organization formed by the consolidation of the A. F. Gilmore and Gilmore Petroleum companies. L. Hoffman-Pinther has been named advertising manager.

FRANKLIN S. TERRY, co-manager of the National Lamp Works, Nela Park, Cleveland, was elected vice-president, and E. G. Tremaine, also co-manager of the National Lamp Works, was elected a director of the General Electric Co., Schenectady, N. Y., at a meeting of the board of directors held in New York City, June 22.

WHITING CORP., Harvey, Ill., has opened a district sales office in Birmingham, Ala., in charge of W. R. Hans as district manager. The Birmingham office will handle sales in Alabama, Georgia, Tennessee and northern Mississippi for the Whiting Corp. and its

subsidiaries, Grindle Fuel Equipment Co. and Swenson Evaporator Co. The Company also plans to open on July 1 a district sales office in Cleveland, Ohio, in charge of R. P. Dryer.

Equipment and Materials

Rugged Construction a Feature of 21-E Paving Mixer

Ruggedness resulting from the use of oversize shafting and other parts so as to prevent operating delays due to breakdowns is featured by the Ransome Concrete Machinery Co., Dunellen, N. J., in its latest model of 21-E paving mixer.

In this mixer all turned shafting is of 0.3-0.4 high carbon steel with diameters of 5½ in. for the traction shaft that drives the crawlers, 4½ in. for the traction speed change shaft, 4½ in. for the traction reverse shaft, 3½ in. for the mixer drum drive shaft, 4½ in. for the drive shaft for the crawler treads, and 3½ in. for both the power loader winding drum and the boom bucket winding drum shaft.

The power equipment consists of a 40-hp. four-cylinder Hercules gasoline engine, which, it is claimed, may be stalled without bending the shafts or breaking the sprockets and gears. Heretofore, the company points out, steam power of 15 to 20 hp. has been used extensively for driving paving mixers.

Many of the breakages as well as delays to paving mixers have been caused, it is said, by trying to transmit 40 hp. from a gasoline engine through shafts and gears designed for only 20-hp. steam engine operation.

The main frame consists of longitudinal members and has a three-point suspension on the axles to avoid undue strains during traveling over rough roads. The mounting is of the crawler type.

The loading hopper is constructed of ½-in. steel plate and is served by a power operated derrick with a reach of 14 ft. from the center of the paver to the center of the industrial tracks alongside for handling batch boxes. Delivery of the mixed concrete is by means of a 20-ft. boom and a bucket of 30 cu.ft. capacity of the bottom-dump spreading type. Overall dimensions of the mixer, including loader, are: Length, 20 ft. 9 in.; height, 3 ft. 11 in.; width, 10 ft. 1 in. The weight is 33,250 lb.

Crane Convertible to Shovel

A crawler-mounted locomotive crane, convertible to a 3-yd. revolving shovel, is one of the new products of the McMyler-Interstate Co., Bedford, Ohio. The crane is steam operated and is fitted with the necessary mechanism for hoisting on either of the two main drums, operating a two-line bucket, lowering or raising the boom, rotating the crane and traveling. The machine

may be equipped with a boom 30, 35, or 40 ft. long, and its overall dimensions are length 16 ft. 7 in., width 8 ft. 10 in., and height 13 ft. 2 in. The operating weight of the crane is 55,000 lb. The crane has a capacity of 20,000 lb. at 12 ft. radius. A feature of the design is the accessibility of all parts for adjustment and repair.

The various operations of the crane are actuated by a 6 x 8-in. double-cylinder, non-reversing engine. Link motions and reversing valves are eliminated through the use of right- and left-hand clutches for raising and lowering the boom, for slewing, and for propelling. For operation of the steam shovel the equipment includes a 17 ft. 6-in. boom and a 12 ft. 6-in. dipper handle.

Rubber-Tired Trailer Built for Transport of Heavy Equipment

For the quick transportation from one job to another of heavy construction equipment such as steam shovels, cranes, road rollers and concrete mixers, the Douglas Transfer Co., hauling contractor of Pittsburgh, is using a four-wheeled truck trailer with solid rubber tires having a carrying capacity of 50 tons, made by Rogers Bros. Co., Albion, Pa. The overall length of the trailer, from the end of the drawbar to the rear of the deck, is 26½ ft., the overall width 13½ ft., and the height from pavement to the top of the platform 22 in. The frame is composed of 8-in. steel H-sections and heavy 8-in. ship channels. The solid rubber tires are 14x40 in.

The Douglas company cites the following two instances of the performance of its trailer: A 3-yd. Erie steam shovel was moved a distance of 11 miles over hilly roads in 3½ hr. actual hauling time. It was necessary to load and unload the shovel three times dur-

ing this trip on account of overhead obstructions of bridges, steam pipes and wires. Another trip of 12 miles over steep grades and under unfavorable weather conditions delivered a 20-B Bucyrus shovel in 5 hr. and 30 min. actual hauling time.

Publications from the Construction Industry

Gasoline Engines—STOVER MANUFACTURING & ENGINE CO., Freeport, Ill., describes in a 24-p. illustrated catalog its line of gasoline and oil engines from 1 to 30 hp. Most of the models shown are stationary types. One of the units is a 13-hp. engine direct connected to a Myers pump and several of the outfits from 1½ to 12 hp. are mounted on four-wheel trucks, including one portable wood-sawing rig.

Truck Motors—GEORGE HAISS MANUFACTURING CO., INC., New York, has issued a 27-p. catalog, illustrated, featuring its path-digging truck loader for handling crushed stone, sand, gravel, coal and other loose materials. The loader is of the continuous bucket type mounted on crawlers. One of the machines illustrated is equipped with a measuring hopper at the discharge end. Several pages are devoted to a presentation of figures on loading capacities and costs as compared with hand shoveling.

Paint—E. I. DU PONT DE NEMOURS & CO., INC., Philadelphia, has published a 200-p. illustrated book entitled "Principles and Practice of Upkeep Painting," written to serve as a practical aid to plant superintendents or others responsible for the maintenance of industrial property and equipment and as a help to architects and engineers in the protection of new construction. It covers modern painting practice for all types of exterior and interior surfaces. The data are presented in 28 chapters, taking up such subjects as the preparation of the surface for painting, methods of application, treatment of both wood, metal and cement concrete surfaces, light reflecting finishes for walls and ceiling. There is an important discussion of spray painting and suggestions on how to operate a paint shop and provide for periodical paint inspection. For every kind of use a specific type of paint is recommended. The book contains a supplement in the form of a color chart.

Business Side of Construction

FACTS AND EVENTS THAT AFFECT COST AND VOLUME

Public Bond Sales in July Far Below June Aggregate

The reaction from the exceptional activity displayed during June in the issuance of state and municipal bonds coupled with the customary dullness which comes at this season and the weakness of the security markets on the Stock Exchange, according to the monthly review in the *Commercial and Financial Chronicle*, New York, kept the aggregate of new municipal issues during July down to \$59,107,271. This is \$100,578,816 less than the June aggregate. The falling off was not confined to states and municipalities in

Of the forty representative bond issues included in the tabulation on this page, none was sold at par, three sold below par, the balance above par. The yields ranged from 4.16 to 5.37, and the rate of interest from 4 to 5½ per cent.

National Lumber Trade Steady

Although the national lumber trade, as reflected by reports from 398 of the larger commercial mills of the country to the National Lumber Manufacturers' Association here, fell off slightly last week, new business was up to the average of May and above that of June and

of the reporting mills have a normal production figure for the week, and according to that their actual production was 105, shipments 96 and orders (new business) 90 per cent.

Car Service Division Reports Record Freight Loading

According to a report issued Aug. 13 by the Car Service Division of the American Railway Association, the railroads of the United States on July 31 had 76,453 surplus freight cars in good repair and immediately available for service if necessary despite the fact that during the week which ended on July 28, 1,041,044 cars were loaded with revenue freight, the largest number for any one week in the history of the country. When a record loading of 1,018,539 cars was established during the week of October 14, 1920, which

this country but extended to Canadian municipal and Provincial bonds.

The largest issue during the month, \$3,500,000 5½s., was sold by the Everglades Drainage District at a price reported to be 95. There were two issues for \$2,000,000; one by the state of Michigan for highway improvement bonds, the other put out by Cook County Forest Preserve District, Illinois.

The number of municipalities emitting long term bonds and the number of separate issues during July 1923 were 333 and 478 respectively. This contrasts with 425 and 594 for June, 1923; and 591 and 752 for July, 1922.

the July of 1921. While production declined from the high levels of May and June it is still in excess of shipments and orders. The general lumber movement is larger than at this time last year. Unfilled orders of the West Coast Lumbermen's Association's mills increased 5,000,000 ft. and those of the Southern Pine Association decreased 41 per cent, as compared with the preceding week.

For all the reporting mills shipments were 88 and new business 82 per cent of production last week; for the Southern Pine mills, the percentages were 95 and 82, respectively, and for the West Coast mills 93 and 91. Most

record remained until this year, a car shortage of 69,517 cars was reported.

The total number of surplus freight cars on July 31 was a decrease of 3,257 compared with the number on July 22. Of the total number on July 31, 57,831 were box cars, a decrease of 3,388 in approximately a week; while there were 6,546 surplus coal cars in good repair, an increase of 1,379 within the same period. Surplus stock cars numbered 3,437, a decrease of 846 since July 22, while a decrease for the same period of 648 was reported in the number of surplus refrigerator cars which brought the total for that class of equipment to 7,615.

To Reduce Industrial Accidents

In order to reduce industrial accidents in New York State, formation of an educational council to co-operate with the state labor department has been decided upon. Educational campaigns are to be carried to public schools, high schools, night schools and various vocational and continuation schools. Exhibits will indicate accident causes and how they may be avoided.

Large Contracts Let During Week

Among the week's announcements of contracts awarded in Construction News, pp. 89 to 97, are the following:

Store building, Los Angeles, Calif., to MacDonald & Kahn, \$1,000,000.

Store, office and hall building, Chicago, Ill., to McKeown Bros., 112 West Adams St., \$1,250,000.

Sewage treatment works, Chicago, Ill., to J. Griffiths & Sons Co., 112 West Adams St., \$5,602,636.

Bids Wanted on Big Jobs

Among the projects on which bids are either asked or will soon be called for, in Construction News, pp. 89 to 97, are the following:

Wharves, Houston, Tex., for Houston Port District, \$4,000,000.

Apartment-hotel, Chicago, Ill., for G. G. and E. C. Anders, \$1,000,000.

Sewage-treatment works, Chicago, for Sanitary District of Chicago, \$5,602,636.

Weekly Construction Market

THIS limited price list is published weekly for the purpose of giving current prices on the principal construction materials, and of noting important price changes on the

less important materials. Moreover, only the chief cities are quoted.

Valuable suggestions on costs of work can be had by noting actual bidings as reported in our Construction News section.

The first issue of each month carries complete quotations for all construction materials and for the important cities. The last complete list will be found in the issue of Aug. 2; the next, on Sept. 6.

Explanation of Prices—Prices are to contractors in carload lots unless other quantities are specified. Increases or decreases from previous quotations are indicated by + or — signs. For steel pipe, the prevailing discount from list price is given; 45-5% means a discount of 45 and 5 per cent. Charge is 15c. per 100 lb. for cutting reinforced steel into 2-ft. lengths or over.

New York quotations delivered, except sand, gravel and crushed stone, alongside dock; common lump lime, in 280-lb bbl net, and hydrated lime f.o.b. cars; tile "on trucks"; linseed oil and cast-iron pipe f.o.b. Labor—Concrete laborers' rate, 93c.; building laborers (pick and shovel men) 75c. per hr.

Chicago quotes hydrated lime in 50-lb. bags; common lump lime per 180-lb. net. Lumber delivered on job.

Minneapolis quotes on fir instead of pine.

Brick, sand and hollow tile delivered. Cement on cars. Gravel and crushed stone quoted at pit. We quote on brown lime per 180-lb. net; white is \$1.80 for Kelly Island and \$1.70 for Sheboygan. Common labor not organized.

Denver quotes on fir instead of pine. Cement "on trucks"; gravel and sand at pit; stone on cars; lime, brick, hollow tile and lumber on job. The price is at warehouse. Linseed oil, delivered, in iron bbl. Common lump lime per 180-lb. net.

Atlanta quotes sand, stone and gravel per ton instead of cu.yd. Common lump lime per 180-lb. net.

Dallas quotes lime per 180-lb. bbl. Steel, cement, cast-iron pipe and crushed stone f.o.b. cars, other materials delivered.

San Francisco quotes on Heath tile, size 5 $\frac{1}{2}$ x 8 x 11 $\frac{1}{2}$. Prices are all f.o.b. warehouses except C. I. pipe, which is mill price

plus freight to railway depot at any terminal. Common lump lime per 180-lb. net. Lumber prices are to dealers in yards at San Francisco, for No. 1 fir common.

Seattle quotes on Douglas fir (delivered) instead of pine. Lump finishing lime per 180-lb. net. Hollow building tile delivered. Hydrated lime in paper sacks. Sand and gravel at bunkers.

Montreal quotes on pine lumber. Sand, stone, gravel and lump lime per ton. Cement, lime and tile are delivered; sand, gravel and stone on siding; brick f.o.b. plant; steel and pipe at warehouse. Hollow tile per ft. Cement price is in Canadian funds (the Canadian dollar stands at 87.78). Bag charge is 80c. per bbl. Discount of 10c. per bbl. for payment within 20 days from date of shipment. Steel pipe per 100 ft. net; 3-in., \$47.43; 6-in., \$119.

A Little Review of the Situation

The very real likelihood of an industrial depression did not dissolve into a mere possibility until the middle of July, when *Engineering News-Record's* Construction Barometer said: "When a number of red flags are displayed for a considerable period of time it is likely that the danger indicated will be avoided." This danger in the construction industry was a large-scale buyers' strike caused by high cost.

There was a buyers' strike in the larger centers, but the construction thus curtailed was proportionately small, and the actual volume (not mere money value) of construction in 1923 is well ahead of 1922.

Interest centers chiefly in construction cost as the critical element of the situation. Since October, 1922, it has risen until at the beginning of June it reached a point 121 per cent above 1913. It has maintained that level to date and is 28 per cent above a year ago.

Construction cost is high because the country is oversold on building materials and the demand for labor is such as to encourage high wages. Last year's construction amounted to \$4,500,000,000. Contracts awarded in the first half of 1923 reached three billions.

The only practical relief is in producers of

construction materials catching up on their orders. Contract-letting declined 14 per cent in July, with indication of a further falling off in August. This is, of course seasonal and should furnish the breathing space needed to fill present orders. The unfilled steel tonnage curve (see The Construction Barometer, July 26) indicates this catching-up process on the part of the United States Steel Corporation. That general business remains active is shown by heavy freight car loadings. Total loadings for the week ended July 21 was 1,028,927 cars, which is the heaviest in the history of railroading.

Number 8

Has the Public Control?

THE negotiations between the coal miners and operators now in progress at Atlantic City will demonstrate as never before whether public opinion is an effective force in the settlement of labor disputes. The people, generally speaking, have not taken sides in this controversy; few outside those directly concerned know anything about the issues involved. What the mass of the people do know is that anthracite coal, hitherto a necessity for a considerable and important part of the country, is controlled absolutely by half-a-dozen men sitting around a table at a beach hotel. On their ability to agree rests the comfort and health of many millions of American citizens. These citizens, we believe, are agreed that the questions in dispute are arbitrable and they expect them to be settled but, having in mind the hardships of last winter, they are willing that the government, through the President, go to any means, however extreme, to force the production of anthracite in the event that those in control cannot agree. Within a week we shall see whether Mr. Lewis and Mr. Warriner are willing to force the coal business into government control.

The Ruhr Deadlock

HOWEVER much one sympathizes with the French effort to extract proper reparation from the Germans the impression grows that the occupation of the Ruhr is a failure, unless it is a preliminary to annexation, though how any Frenchman can desire such annexation with the memory of Alsace-Lorraine and its fifty years of "revenge" in mind is more than the boundary-secure American can imagine. As an industrial move, however, the French policy is playing into German hands. For a certain length of time—no one knows how long—the Germans can continue to refuse to produce and can concentrate all their effort on permanent improvements, which will return increased revenues when, or if, they ever get back control of their own industry. The deadlock grows—but with it grows the feeling that the whole reparations question must be taken out of the hands of the statesmen, or politicians (which is a more exactly defining word), and turned over to an international group of business men to settle.

Speeding-up Through Motor Traffic

ONE WAY of solving the problem of traffic congestion in small cities and towns is suggested by M. O. Eldridge, executive chairman of the American Automobile Association, after an inspection trip in the New England States. Mr. Eldridge says: "Oftentimes through a careful study of the traffic situation a route through the town can be selected which will avoid the heavily congested streets. The route selected may not be the most direct and may require the use of a number of different streets. However, if the route is plainly

marked, tourists will use it in preference to stopping at corners and inquiring their way. The situation I found in some of the cities and towns in the New England States can be duplicated all over the country. The impression which a well laid out and well marked route through town will make on the visiting motorist will amply repay any community for the study and effort required to bring it about. A tourist never fails to advertise a town where he found it easy to get in and out again." This recommendation is similar to that made in the editorial review of the traffic situation in *Engineering News-Record*, June 21, 1923, p. 1070. The success of the method in towns where it has been tried has been so general that most towns and cities will do well to make a special study of this feature and see if they can outline a route that will divert through traffic from their over-congested streets.

Federal Contract Provides Arbitration

A DECIDED advance in the equities of contractual relations is marked by the decision of the Interdepartmental Board of Contracts and Adjustments to provide an arbitration clause in federal government construction contracts. In these contracts in the past there has been no appeal from the decision of the contracting officer. Now the right of appeal to department heads is extended in matters of time and of the financial consideration involved. Coming from the stronghold of drastic contracts and exacting supervision this concession of arbitration privileges assumes almost an epochal significance. It should stimulate action, long delayed, by a number of engineering associations which now have arbitration clauses before them for consideration.

Too Much Standardization

EX-PRESIDENT Eliot of Harvard, in a recent letter to the *New York Times*, deplors the current craze for standardization as a deadening influence on social development. In particular, he is concerned with the evil effects on a proper individualism which will result, he thinks, from our growing standardization of the worker's operations. It is a fair question whether this phase of the standardization evil is not being over-emphasized. Is it a fact that the worker is more deadened by eight hours of one operation than by twelve or more hours of varied tasks? The man in the story who said that his qualifications for a machinist's job were that he had spent three years tightening the right forward holding-down bolt on Ford engines doubtless did not get as much out of his work as did the mechanic who built Stephenson's locomotives, but certainly he sees more and enjoys more in his sixteen daily hours away from the shop than did his predecessor in the ten or twelve which he had for leisure and sleep. This world can never return to the individual artisan. The

best that can be done is to move toward an amelioration of working and living conditions and an increase of leisure and pay which will make up for the loss in the joy of the work itself. At the same time, Dr. Eliot does well to sound a warning that standardization is not the ultimate ideal in every phase of life, which is a too general tendency especially in technical circles. The distinction between simplification of style and pattern and complete standardization is too little appreciated. It is eminently desirable to have the sizes and shapes of steel I-beams reduced to a minimum. It would be a most restrictive binder on engineering initiative to insist on the establishment of a few standard types of bridges. And yet just this latter kind of thinking is apt to result from the glorification of the standardization idea.

State Supply of Road Materials

BOLD seizure of the road-building materials supply situation is apparently contemplated by the Missouri State Highway Commission. A month ago the announcement was made that the commission would receive bids for furnishing, for one or several years, all cement required, or, as an alternative, for providing the state with one or two cement manufacturing plants. On Sept. 5, it is now announced, the commission will receive bids for furnishing for one year or for a term of years, all sand, gravel and crushed stone required for road construction. Except that Missouri contemplates supplying all materials and not cement alone its plan is not different than that in force for some years in Illinois. Its threat to operate state cement mills is nothing different than is being threatened by half a score of states. The significance of the present action is that it indicates the hardening will of state highway administrations to rid themselves of the obstacles of alleged unfair prices, insufficient production and uncertain transportation of road-building materials. Virtually it is an attempt to stabilize for road construction the materials market. There is precedent for state purchase and supply of road-building materials. Apparently the practice has been satisfactory. The uncertain venture is state manufacture of cement. Opinion of some of its complexities was given in the issue of March 22, 1923, p. 519, and nothing has since occurred which materially modifies that opinion. The vision of state manufacture, as a certain means of relief from present difficulties of cement supply, will not, however, be dispelled by anything that anyone can say. The plan has to be tried out. Perhaps Missouri will be the state which will undertake the experiment. It is certain, if it does, that a number of other states will form an interested audience.

Amateur Engineering Again

FROM California there comes a story of amateur engineering which fortunately had no sequel of toll of life or injury, though it did involve sufficient loss of money to make it a good example of how not to do engineering work. A man who owned a large ranch in Humboldt County, near Eureka, not conveniently accessible to the rest of the county, succeeded in getting through a county appropriation for the construction of a 280-ft. span bridge under designs prepared by a local "engineer" in no wise qualified to undertake such work. The bridge was built and the ranch sold, after which the chief actor in the incident lost all interest in the

structure. The superstructure of the bridge was of simple suspension design and seems to have been quite satisfactory, but the piers were founded on soft material and when the rainy season came they began to slip and slide. One of them moved down the channel and partly tipped over. The county had expended \$25,000 on this bridge, and when it threatened to disappear in the river the county authorities called in a competent local construction company with emergency orders to salvage as much of the bridge as possible. This company went in and took down the entire superstructure and stored it for the winter or at least pending the reconstruction of proper piers. Possibly when they put back the bridge the county will think that a regular engineer will pay. Such an engineer can design a movable bridge; it takes one of his amateur imitators to design a removable one.

An Explanation Which Does Not Explain

DR. WORK'S explanation of the reasons for his removal of Arthur P. Davis from the Reclamation Service, as given in his letter to the American Society of Civil Engineers, is only a repetition, over his own signature, of the views that have been credited to him in interviews. To be completely understood, however, it should be read along with the "memorandum for the press," just issued by the Department of the Interior and reproduced along with the letter in the news section of this issue. The letter and the memorandum taken together make a fair prospectus of the campaign that Dr. Work purposes to follow in justifying his political reorganization of the Reclamation Service.

To the Secretary of the Interior government reclamation comprises two distinct, and apparently mutually exclusive, parts—the "building of dams and ditches" and the "problem of the water users." The former he considers the whole duty of the engineer, but for the latter he would secure a "practical business man." No more condescending definition of the function of the engineer was ever written than this letter, and the workings of the author's mind in depreciation of the engineer and the magnification of the business man are more fully revealed in the memorandum.

This memorandum is a gem. Intended obviously to impress the casual reader with the radically different type of mind that is now in charge of government reclamation, it proceeds to recite as the novel items of a new policy precisely the same details in irrigation design and operation that have always governed the practice of irrigation engineering. It is not necessary to repeat those details to an engineering audience, but for others it may be well to say that irrigation engineering involves the proper selection of site, not only to insure the water supply but also to insure the proper agricultural and marketing conditions, the safe and economical construction of the physical elements of the project, the careful adjustment of the water service to the needs of the crops, the study of the agricultural processes for the education of the farmers, and finally the nice balance of human relations which is necessary to insure the well being of the settlers and their proper repayment of the funds to the government. These elements make up irrigation engineering. It is only when they become dignified with the magic words "business administration" that they warrant a special "memorandum for the press."

Government irrigation has not been an unqualified success. In that statement Dr. Work is correct. Irrigation on such an extensive scale as practiced in the West is a new art which requires learning with its development. Engineers today know much better how they should build and operate irrigation works than they did twenty years ago and in that degree they are to blame for the failure of complete success. Quite as much of the blame, however, lies in the law itself and in its administration by those superior to the engineer. Such disabilities would in nowise be removed by an assumption that the engineer is merely the builder of dams and the digger of ditches and that the larger policies of reclamation can be determined by some overhead business management which works quite independent of those who conceive and execute the physical elements of the irrigation scheme. Design, construction and operation are inextricably woven in irrigation as they are in all other engineering work. In the design and in the construction one type of engineering activity is required. In the operation and in the control another type is required, but the two are equally engineering functions.

All of this has been sufficiently obvious to the engineers who are interested in or have been connected with irrigation work. The opposite contention—the one held by Dr. Work—that the administration of irrigation requires a business man, has a certain appeal to that very large body of people who are hypnotized by this demand for a business administration of everything. It is only when the advocates of this plan attempt to put down in words a program for administration that they find difficulty in expressing the distinction between what they advocate and what has been practice. The “memorandum for the press” is the best illustration of this difficulty of specifying what is a business administration that could be offered in defense of the engineer.

The Mystery of Fatigue

FROM the time of the earliest researches into the failure of materials through the effect of a very large number of load repetitions, carried out by Wöhler and Bauschinger, the subject of fatigue has remained enveloped in its cloak of mystery. The elaborate investigations of recent years have supplied more exact and more complete facts on fatigue, but they have not done much toward dispelling the mystery. Not the slightest approach has been made toward an understanding of what goes on in the metal that causes it to break after 5,000,000 but not after 5,000 repetitions of a particular load; and all the new facts developed, such as that the repetition of loading strengthens rather than weakens the material, merely add to the difficulty.

From the standpoint of the further exploration of fact, the two series of investigations summarized in this issue—those of McAdam at Annapolis and those of Moore at Illinois—are of great importance and interest. To the civil engineer in particular the research work now begins to have tangible value, because for the first time it touches upon the subject of endurance range under other conditions than full reversal of stress. In both the Annapolis and the Illinois work of the past year there may be found certain definite conclusions concerning the general endurance range,

and while differing in form they are not far from agreement, to the effect that the total stress range of endurance is independent of the absolute values of maximum and minimum stress, up to the point where the upper limit reaches the elastic limit (or some other critical stress) of the material.

A further fact of decided importance may be concluded from the Annapolis work, namely, that stress attack of quite different kinds is subject to substantially the same laws as to endurance. Tests under repeated torsion, repeated impact and reversed bending showed no essential difference, except in the numerical measure of the critical value for the particular kind of stress concerned. This fact, which rests on a large amount of remarkably consistent and harmonious experimental material, will keep the subject clear of much confusion that otherwise would involve it.

Nothing has been uncovered in the past two years' experimentation to weaken the force of the conclusion previously arrived at in the Illinois work that the endurance limit is identical with a critical stress value which may be determined in a few minutes by its relation to the rate at which heat is developed in a specimen subjected to repeated loading. Below the critical stress, heat is developed at one rate, while above this limit it is developed at a greater rate. That this “heating limit” is identical with the endurance limit which requires many months of testing to determine it may now be considered to be fully established for steel, since all the Illinois data, without exception, agree with it.

This established fact almost inevitably leads to the conclusion that the more rapid heat developed corresponds to some destructive action in the interior of the testpiece, bringing about a gradual weakening of the piece until its final rupture. It is, therefore, disconcerting to be told that no test, microscopic examination or other method of study has been able to reveal the slightest change in the material in the course of the repeated application of stress just above the endurance limit. The destructive action evidently must be of such nature as to escape any means of discovery we yet are able to apply. But is there a destructive action in progress at all? McAdam's work shows that if a stress at or just below the endurance limit is applied as many as ten million times, the testpiece is strengthened, not weakened; it is able to endure without failure many additional millions of stress repetitions at a much higher stress, far above the original endurance limit. The nature of this strengthening effect is as much of a mystery as the weakening which is made manifest by this fatigue failure, but it seems likely that the two effects are in some way closely related.

For the present the results of research seem to sum up in the fact that we have learned certain things about endurance, but are quite unable to correlate these things with other scientific knowledge, so that the subject remains a deep mystery. Doubtless this mystery conceals within itself a great many additional facts about endurance, and it may be that we are not yet within even fair reaching distance of knowing the essential phenomena of this important mechanical action. Research is bound to continue, therefore, at the full present rate—or, better still, at a greatly accelerated rate, to engage many more workers and thinkers than are now active in the subject.

How Oklahoma City Water-Works Dam Withstood Floods

Twice the Designed Capacity Passed Safely—High Water Record Broken Three Times in Month—Repairs Planned, Spillway to be Made Open and Bank Protection to be Extended

BY A. S. HOLWAY

Chief Engineer, Water Department, Oklahoma City, Okla.

JUNE FLOODS on the North Canadian River broke previous records on three successive rises at Oklahoma City. They washed out practically all bridges over it in Oklahoma and seriously threatened the water-works storage reservoir at Oklahoma City. An amount equivalent to nearly twice the capacity of the spillway facilities passed the dam and the water rose to within 6 in. of the top of an extremely long earthen embankment. Driftwood and floating bridge timbers caused much anxiety. The water conduit to the city paralleling the river below the dam was nearly washed out. Sandbags by the thousands saved the day, being used extensively at the ends of the concrete section of

in. near the eastern end of the Oklahoma panhandle to 15 in. at the extreme west end of the State and in northeastern New Mexico. The average rainfall, total area considered, is probably not far from 20 in.

Excessive rains fell throughout the watershed May 21 to 23, with an average of 3.52 in. for thirteen stations. The heaviest rain, according to the U. S. Weather Bureau records, was 4.68 in. at Woodward. Newspaper reports indicate that there was more than 5 in. at many places at which there are no rain gages and from 8 to 10 in. at certain points.

Runoff from these storms was unusually heavy and rapid, raising the river gage at Oklahoma City to 13.9 ft. on May 22, the highest record since this gage was established. As the flood from the tributaries upstream passed down the river the gage at Oklahoma City showed 15.9 ft. on May 29, again the highest of record on this gage. The water from this flood covered the bottom lands and receded very slowly. Rain continued to fall over the watershed and on June 8 the river began rising rapidly at Woodward, reaching its crest at this station on June 10. The Weather Bureau records (see Table I) show general precipitation throughout the watershed, with 2.3 in. at Woodward and 3.25 in. at Canton, June 7 to 9. The records from other stations farther up the stream are incomplete for this period though the precipitation was doubtless heavy. The crest of the flood passed rapidly downstream reaching Canton at midnight on June 10, Reno Junction at 5 p.m. on June 12, the water supply reservoir at 10 p.m. on June 13 and Oklahoma City at noon June 14. At the latter place the gage reading was 16.3 ft., establishing a new record for the third time within thirty days.

The water supply reservoir was constructed in 1916-18 and the general layout is shown in the sketch. The structures consist of a hollow dam across the river valley approximately 1,100 ft. long, at the west end of which is an earthen dam with concrete core wall 1,200 ft. long.

Under ordinary conditions the river water flows through a shallow sedimentation reservoir, formed by an earthen diversion dam on which are the highway and interurban line. By this dam the water is diverted to the east side of the sedimentation reservoir, whence it flows through a bypass canal on the east side of the main reservoir to the flood control works which are located at the east end of the main dam. The 2-mile bypass canal is separated from the main reservoir by an earthen embankment originally built with an 18-ft. crown.

Flood control works at the lower end of the canal in the end of the dam consist of four electrically-operated sluice gates, 14 ft. high, and 9 ft. wide, having an estimated capacity of 8,000 cu.ft. per second. Four auxiliary spillways have an estimated capacity of 2,650 cu.ft. per second. These spillways are surmounted by a walkway across the dam. An emergency spillway of

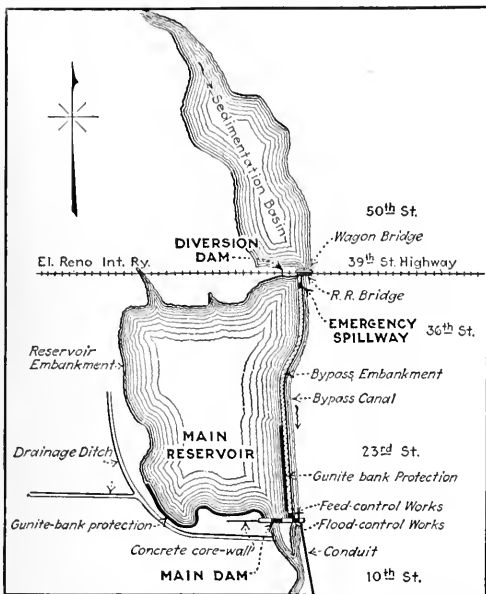

WATCHING A PILE BENT OF THE INTERURBAN "GO OUT"

Bridge floor planks removed (1) to get at drifting logs and haul them out by tractor and wire cable operating along upstream side of approach, (2) to salvage and prevent their floating downstream two miles and lodging against the dam spillways.

the dam, on top of the various earth embankments and in protecting the city conduit. While the information of the rainfall over the watershed is meager, observations taken by the Weather Bureau indicate only moderately heavy storms in June but heavy ones in May which saturated the area.

The North Canadian River is formed by the junction of Beaver Creek and Wolf Creek, which rise in northeastern New Mexico and northern Texas respectively. The 10,000-sq.mi. drainage area is situated principally on its upper tributaries through the panhandle of Oklahoma and Texas where it varies from 30 to 75 miles in width. For 100 miles above Oklahoma City the watershed is extremely narrow, in some places not more than a mile in width. Except for Beaver and Wolf creeks the tributaries are short, usually not more than 10 miles long. The watershed is composed in most part of a porous sandy soil, approximately 35 per cent under cultivation. The topography is more or less rolling in character. The river channel is very crooked and the rainfall is light, producing a sluggish flow.

The average annual rainfall in Oklahoma City is 31 in. per year, but the principal tributary drainage area lies in a region of smaller rainfalls, ranging from 25

OKLAHOMA WATER-WORKS STORAGE RESERVOIR AND SEDIMENTATION BASIN

7,850 sec.-ft. capacity at the north end of the bypass canal through the bypass embankment is so constructed that it will come into action at the time the flood control spillways start to overflow. Water flowing through this spillway passes through the reservoir to the spillway over the main dam. Feed control gates at the lower end of the bypass have a capacity of 1,220 cu. ft. per second, making a total capacity of all available gates and spillways of 19,720 cu. ft. per second.

In an engineer's report dated 1913 covering this project we read that the greatest recorded flow to that date was 3,640 sec.-ft. In the 1916 report covering the same project the engineer states: "We are undertaking to control the flood water of a stream capable of

ing morning the flood control gates and spillways were operating at their maximum capacity. Water began to run over the walkway across the entire length of the bypass dam. At the crest of the flood this walkway was finally overtopped by 1.8 ft.

Water began to run over the abutment on the east side of the dam and sand bags were called into use to prevent cutting away the earth to the east and below this abutment. The bags were carried up to a height of 3 ft. before the crest of the flood was reached. Soon after the walkway at the flood-control works was overtopped the water began to flow over low places in the embankment separating the bypass from the reservoir. Sand bags were again called into service and these low places were raised in such a way that the water flowing over this embankment was forced to flow 9 in. deep over the lower 5,000 ft. next to the dam, a section of the embankment recently improved by the construction of gunite revetment work, as described in *Engineering News-Record*, May 17, 1923, p. 880. The quantity of water carried over this embankment at the crest of the flood was estimated at 10,000 sec.-ft.

Throughout the day floating logs piled against the highway bridge at Thirty-ninth Street. This drift coupled with a severe scouring action at the bottom of the channel gradually weakened this structure until several 4-pile bents were undermined and finally went out, carrying with them the several 5-pile bents of the interurban bridge directly below. [Observations by a representative of *Engineering News-Record* in the afternoon and again about 8 p.m. disclosed that the first sign of weakness in the highway bridge was a slight curve, downstream, in the alignment. Shortly afterward the bridge started to sag at one of the undermined bents. Finally the bent passed out from below the bridge quite slowly and then floated against the interurban bridge. None of the structures went out with a rush. One of the interurban bents after floating from under the intact floor structure, turned end-for-end, the sharp ends of the piles giving a pinwheel effect in the rotation.—EDITOR.]

When it became evident that these bridges were going to fail the pipe handrails on the walkway across the bypass dam were cut to keep this drift from piling

TABLE I—DAILY PRECIPITATION FOR JUNE 1923 ON THE NORTH CANADIAN RIVER IN OKLAHOMA

* No report—No doubt heavy.

discharging in excess of 4,000 sec.-ft." This amount is equivalent to 0.4 sec.-ft. per square mile of drainage area. In October, 1920, after the dam was placed in operation a flood occurred carrying 8,750 sec.-ft. or 0.875 sec.-ft. per square mile. On May 28 of this year the flow was 10,000 sec.-ft. at the crest of the flood, or 1 sec.-ft. per square mile. On June 13 the crest of the flood carried a total of 33,700 sec.-ft. or 3.37 sec.-ft. per square mile. The size of this flood takes on additional significance when we consider that during a period of three months of the summer of 1922 the flow of the river into the storage reservoir varied from 1 to 1½ sec.-ft.

In the afternoon of June 12 the water at the reservoir began rising very rapidly and by 9 o'clock the follow-

WATER OVERTOPPED THE CONCRETE WALKWAY
OVER THE HOLLOW DAM

Spillway sections both sides of gatehouse and at far end of concrete section flooded out. Railing near gate house cut to prevent driftwood lodging against it. Concrete apron below flood-control gates was washed out entirely.

against the dam and flooding the spillways. A large proportion of the wreckage from these bridges was hauled to shore with tractors. That which got away was carried by the side current and lodged on the bypass embankment. Some of it passed over the top of the walkway and a small amount lodged against the spillways at the flood control gates. Two large logs were lodged in the flood-control gates and could not be removed until the flood receded.

The water passing over the top of the bypass embankment and through the emergency spillway gradually filled up the main reservoir until the spillway and wasteways were carrying their full capacity. The walkway the entire length of the main dam was finally overtopped 6 in. Sand bags were used to raise the walkway at the west end to prevent the water from dropping down close to the west end of the main dam, where it would have gradually washed away the earth and exposed the core wall, eventually emptying the reservoir around the west end of the concrete dam.

A large portion of the west side and south side of the main reservoir is lined by an earthen embankment to prevent the water from flooding the lowlands. A drainage ditch parallels this bank for several thousand feet. The top of this embankment is 1 ft. above the top of the walkway on the main dam. The highest point reached by the water in the main reservoir was therefore only 6 in. below the top of the embankment

OVERFLOW FROM THE MAIN RESERVOIR INTO THE
BYPASS CANAL

The pole line indicates the inside edge of the embankment.

for a distance of approximately 20,000 ft. At some points this embankment is very narrow and a high wind the succeeding day threatened to destroy certain parts of it. Sand bags were again called into use.

One of the particular points of danger from the water supply standpoint was the fact that the conduit line to the city is laid close to the east bank of the river for $\frac{1}{2}$ mile south of the dam. Part of the riprap bank protection 150 ft. below the dam was destroyed by the floods in May. Hundreds of sand bags were used at this point to protect the shore from further erosion and to prevent the destruction of the water-supply conduit line.

In view of the fact that the flood was practically twice as great as the total capacity of all gates and spillways it is remarkable that so little actual damage occurred.

It will be necessary to replace the highway and interurban bridges at Thirty-ninth Street and the riprap bank protection below the spillway on the east side of the river. The concrete apron below the flood control gates was entirely destroyed. Some little wash occurred in spots over the bypass embankment but the gunite protection work remained intact. Plans were immediately started for making these repairs and certain changes to care for future floods which may equal or exceed this flood in severity. In some way the walkway across the flood-control dam must be eliminated to give a free spillway opening that cannot become clogged with drift. The capacity of the emergency spillway and of the spillway discharging from the main reservoir both need increasing. It is further planned to extend the bank protection work to all the earth sections which were so nearly overtopped. A row of piles will be driven across the sedimentation reservoir north of the highway bridge, at a point where the velocity will be extremely low, to catch whatever drift comes down the river. With the low velocity trees and floating debris can be easily removed to shore.

The Engineer in the Cabinet

"What Washington occasionally calls the important big three of the Cabinet are Hughes, Hoover and Mellon. Hughes and Mellon are in this group apart because of the importance of their particular offices, as well as because of their ability. Hoover is in it in spite of the relatively less importance of his Commerce Department, because of his extraordinary personal ability and because, as a matter of fact, he is so well grounded and so indispensable in many big matters that come up outside the limits of his particular official field. As to Secretary Hoover, in addition to his own department, he is everything that is embraced in the dignity and efficiency of the phrase, "a competent workman." He contributes able and faithful trustworthiness for such frequently arising emergencies as coal strikes, unemployment, conservation and a dozen other matters calling for hard work, concentration of mind and immensely varied knowledge. It was one of the comparatively few easing comforts that Mr. Harding had in his difficult Presidency to know that at any hour, day or night, Mr. Hoover was at the end of the telephone wire, subject to call for any emergency. It was a reliance of which Mr. Harding made frequent use."—Mark Sullivan, in the *New York Tribune*, Aug. 6, 1923.

Sledged-Stone Base Developed For Missouri Roads

One-Man Stone Sledged Down, Filled With Spalls and Rolled Gives Cheap and Durable Base From Soft Native Rocks

SLEDGED-STONE base, with penetration macadam or asphaltic-concrete surface, has been adopted as a standard construction on Missouri highways. On the porous, easily-drained soils of large sections of the state these bases are standing up excellently and are being placed at an appreciable saving as compared with crushed stone or hand-placed Telford. Quarry rocks too soft to provide a crushed stone that will wear can be used as one-man stone for sledged base. Limestone has been used commonly but now sandstone is being tried where it is the native rock.

Rock is plentiful in most parts of Missouri, but there is little which has the coefficient of hardness required of crushed stone suitable for modern macadam. In large sizes—one-man stone—the softness is less objectionable than when the rock is crushed. Used as a base and filled with spalls, crushed stone and screenings, the

FIG. 1—STANDARD SECTION FOR SLEDGED-STONE BASE

large stone apparently break down very slowly due to internal movement of the fragments, but crushed bases of this rock grind up quickly. Hence the sledged-stone base has developed as a means of utilizing local rocks. Briefly it consists of large stone bound together and interlocked by sledging after which spalls, crushed stone and screenings are filled into the interstices and rolled firm and smooth.

FIG. 2—SLEDGING THE LARGE STONES INTO PLACE

FIG. 3—SLEDGED-STONE BASE READY FOR SURFACING

The sizes of stone used run about as follows: (1) As large as one man can readily handle, (2) spalls of any size up to 6 in., (3) crushed stone passing a 3-in. ring and (4) screenings which comprise all fragments

passing a $\frac{3}{4}$ -in. ring. The large stone are uniform, spread on a prepared subgrade as of the section shown by Fig. 1. Then men with 10 or 12-lb. sledges, as indicated by Fig. 2, pound down the projecting tops and hammer the stone into contact and interlock. In sledging, the men work to secure as nearly uniform depth and as even a surface as possible. The surface is then rolled with a 10-ton roller to set and interlock the stone still further than did the sledging. Spalls and crushed stone are next spread to level the surface and then the base is rerolled. The screenings are used to fill in remaining hollows and the base is again rolled. Fig. 3 shows the appearance of a finished sledged-stone base. On this any type of surfacing can be laid.

In contracting for sledged-stone base the practice is to pay a unit price per cubic yard for $\frac{1}{2}$ -mile haul and an additional price for each additional $\frac{1}{2}$ -mile haul. Measurement is made at the point of delivery and the price includes loading, unloading, sledging, rolling, etc.—complete base ready for surfacing.

Finish Alaska Topographic and Mining Survey

In the recent extensive work in Alaska by the Geological Survey of the Department of the Interior, 250,000 square miles, or about 34 per cent of the entire Territory, have been topographically surveyed and 200,000 square miles, or 30 per cent, have been geologically surveyed. In addition, detailed geological surveys have been made of sixteen of the largest mining districts totaling 5,000 square miles, including all of the important coal fields and several of the important copper and gold mining districts. Investigations of the water resources have also been made.

Improved Gantry Cranes for the Port of Hamburg, Germany

Unusual Combination of Swinging and Traveling Cranes Increases the Cargo Handling Facilities of the Port

BY E. KRAHNEN
Luisburg, Germany

DDOUBLE cranes of novel design have recently been installed at the port of Hamburg, Germany. They are a combination of a traveling revolving crane on a high superstructure and a straight line crane or transporter. To meet local conditions four combinations have been evolved.

Originally the crab of the straight line crane accompanied the load and carried the winding gear as well as the cabin with the man manipulating the winch (Fig. 1). In later designs a fixed winch located on the gantry is preferred, the operator having his stand on one of the gantry legs from where he can overlook the hold as well as the movements of the load on its way into the shed (Fig. 2). The runway of this type of cranes can be less substantial, a valuable feature if the reach has to be considerable. In a third design the jib of the revolving crane forms a runway for a second

FIG. 5—OLD AND NEW CRANES AT PORT OF HAMBURG
New double cranes are the first four in the foreground; behind them are the radius cranes of 1900 type.

FIGS. 1 TO 4—DIAGRAMS OF THE DOUBLE CRANES

crab. It can be lowered so far that the load may be transported horizontally, thus forming a second straight line crane that can be turned in a convenient angle to the pier (Fig. 3). In some cases a combination of two revolving cranes and one straight line crane is desired. The revolving cranes are placed on each side of the runway girder in such a way that three cranes can work over one hatch. The runway girder is designed so that it can be drawn in behind the edge of the pier. If the reach is large the runway can also be built as a cantilever, capable of being lowered and raised out of the way on a hinge (Fig. 4). These four types of crane show the adaptability of double cranes.

The straight line crane is employed for general cargo that easily passes between the legs of the gantry. It reaches well into the pier and can operate without danger of conflict with the ship's rigging. The load is moved in the shortest way possible and only needs to be lifted to the height required without having to be lifted over deck superstructures as is necessary with revolving cranes while swinging the load. The runway can be designed to reach over two ships allowing direct transfers from the ship to a lighter beyond. Such movements constitute a large part of the traffic of many ports. A revolving crane is not well adapted to this kind of transfer as the ship's masts and yards constitute a serious obstruction to radial movements of any considerable extent. The crab of the straight line crane is usually built for a capacity of $1\frac{1}{2}$ tons, which is sufficient for general cargo. It works with the high speed of 400 ft. per minute and as no superfluous work has to be done upon the load 40 cycles per minute can be easily attained. Under the same conditions a revolving crane could accomplish only 25 cycles and would require more current for the same amount of work. The winch is of a very simple design and well adapted to the rapidity with which the load is moved. The hoisting and crab traveling ropes are taken up by two drums which can be worked separately or simultaneously.

The revolving crane is usually built for a capacity

of 3 tons, a larger load than ships' gear can handle. Loads of nearly double the capacity of the single draft can be handled by two cranes working together.

In order to work a hatch at full capacity two cranes can be so placed together that four hooks are available for one hatch, the two straight line cranes working in the center while the revolving cranes are handling freight at the corners of the hold. By spotting the booms no time is lost in finding the opening of the hold with each successive draft. The revolving cranes can also be working the corners of the hatch while the straight line cranes are handling deck loads.

The longitudinal travel of the whole crane is effected by means of a hand traveling gear where the cranes are placed close together. For cranes that have to travel a considerable distance along the quai an electrically operated gear is provided.

The cranes at Hamburg were furnished by the Demag Company, Duisburg, Germany.

State Aid for Bridges on State Highways

A STUDY of systems of payment for bridges on state highways, made by the legislative reference library in New York State, shows that twenty-seven out of the forty-eight states of the Union have laws under which the state pays or may pay the entire cost of construction of such bridges, while in sixteen the state bears part of the cost. Five pay no part of the cost of state highway bridges. The sixteen which pay part of the cost includes three in which the state share of payment is limited to "state-aid" road bridges. In addition, five of the states which pay or may pay all the cost on bridges and state highways also have provision for the state paying part of the cost on "state-aid" roads. The lists follow:

STATE PAYS TOTAL COST OF BRIDGES ON STATE HIGHWAYS

<i>Alabama</i>	
<i>Arizona</i>	
<i>California</i>	The law is not clear but it would appear that state bears total cost.
<i>Colorado</i>	The law is not clear but it would appear that state bears total cost.
<i>Delaware</i>	
<i>Florida</i>	
<i>Georgia</i>	
<i>Idaho</i>	State may construct at its own cost.
<i>Illinois</i>	
<i>Indiana</i>	
<i>Iowa</i>	The law is not clear but it would appear that state bears total cost.
<i>Kentucky</i>	State is to bear total cost, but counties and municipalities may contribute if they wish.
<i>Maine</i>	
<i>Maryland</i>	
<i>Michigan</i>	State constructs and pays cost of all bridges greater than 30-ft. span.
<i>Minnesota</i>	
<i>Missouri</i>	
<i>Montana</i>	The law is not clear but it would appear that state bears total cost.
<i>New Hampshire</i>	
<i>New Jersey</i>	
<i>North Carolina</i>	
<i>Pennsylvania</i>	
<i>Rhode Island</i>	
<i>South Dakota</i>	
<i>Washington</i>	
<i>West Virginia</i>	
<i>Wyoming</i>	

STATE PAYS PART OF COST OF BRIDGES ON STATE HIGHWAYS

<i>Arkansas</i>	Not to exceed fifty per cent of cost.
<i>Connecticut</i>	From one-third to seven-eighths of cost.
<i>Louisiana</i>	Fifty per cent of cost.
<i>Massachusetts</i>	Three-fourths of cost.
<i>Mississippi</i>	State may pay part of the cost.
<i>New Mexico</i>	Not to exceed fifty per cent of cost.
<i>North Dakota</i>	Fifty per cent of the cost.
<i>Ohio</i>	Cost to be apportioned equally between state and county or township unless the county and township have agreed to pay more.
<i>Tennessee</i>	Contributes a certain share of cost and may require any county to contribute not to exceed fifty per cent of cost.
<i>Utah</i>	Contributes from one-fourth, one-half to full amount of same sum raised by counties.
<i>Vermont</i>	Not to exceed one-third of cost; town pays the balance.
<i>Virginia</i>	Fifty per cent of the cost.
<i>Wisconsin</i>	Fifty per cent of the cost.

(In addition to the above list, *Alabama* has a provision that the state may pay part of the cost instead of all, while in *Idaho* the state may pay one-third and the county two-thirds, instead of the state paying all.)

STATE PAYS PART OF COST OF BRIDGES ON "STATE-AID" ROADS

<i>Kansas</i>	Not to exceed twenty-five per cent of cost.
<i>Nevada</i>	State and county jointly bear cost of construction.
<i>Texas</i>	Twenty-five to fifty per cent of cost; in unorganized counties state may bear all of cost.

(In addition *Delaware*, *Florida*, *Maine*, *Michigan* and *Minnesota*, all included in the first table above, pay or may pay part of the cost of bridges on "state-aid" roads.)

STATE PAYS NO PART OF COST OF BRIDGES ON STATE HIGHWAYS

<i>Nebraska</i>	County maintains whole of state highway system within its borders.
<i>New York</i>	State constructs only culverts 5 ft. or less in length as a part of highway system. New York State, however, while its highway law specifically provides that no bridges over 5 ft. shall be built or maintained as a part of the highway system, has on a number of occasions provided by special appropriation for the construction of certain bridges and has made them a part of the highway system of the state, most recently the Poughkeepsie bridge across the Hudson River.
<i>Oklahoma</i>	County bears entire cost of construction.
<i>Oregon</i>	State loans funds to counties which counties repay in full.
<i>South Carolina</i>	

Scientist Heads New Italian Department

The four Italian government Departments of Industry, Commerce, Agriculture and Labor have been combined in a Department of National Economy, with four bureaus corresponding to the old departments, each headed by a director. Prof. Orso Mario Corbino has been made minister of National Economy and Prof. Arrigo Serpieri has been made undersecretary. Secretary Corbino was nominated professor of physics at the University of Rome in 1918. He became senator in 1920 and minister of Public Instruction in 1921. He has devoted himself largely to water-power development. Prof. Serpieri has specialized in agriculture. Each is an author of technical papers and books.

Endurance of Steel in Tension, Torsion and Impact

Results Show Endurance Under Three Kinds of Stressing Is of Same General Kind, Though Numerical Values Differ

Abstract of a paper by D. J. McAdam, Naval Engineering Experiment Station, Annapolis, presented at the Annual Meeting of the American Society for Testing Materials.

DATA and conclusions which add to prior knowledge of the endurance or fatigue-resisting power of steels were given by D. J. McAdam, of the Naval Engineering Experiment Station at Annapolis. His tests included not only the conventional rotating-beam tests for endurance in reversed bending, but also endurance tests in reversed torsion and tests under repeated impact of a hammer falling with definite amount of energy per blow. The results obtained are remarkably consistent, forming smooth curves and leading to mutually confirmatory deductions. It is shown that (1) the endurance under the three kinds of stressing is of the same general kind, though the numerical

FIG. 2—ENDURANCE OF STEEL IN REVERSED TORSION

the heat treatment of the material and of its internal structure are also illuminated by the test results.

Rotating-beam tests were made on cantilever specimens at speeds of 1,200 to 800 r.p.m. Reversed-torsion tests were made in machines of two different forms, and in most of the sets were run at a speed of 2,140 r.p.m., although check tests covering a large range of speeds and of flywheel inertia showed these factors to be without material influence on the endurance limit. In the impact endurance tests a beam specimen supported at both ends was rotated intermittently, coming to rest after each 90-deg. rotation, and during this rest was struck by a hammer previously lifted by a cam. The frequency ranged from 90 to 600 blows per minute. The weight of hammer and height of fall were adjusted to the desired energy per blow, and this was so controlled as to require from 500 to many million blows for fracture. By a special arrangement still greater energy per blow was provided for, and tests were carried down to the point where a single blow fractured the specimen. Very uniform results were obtained, plotting in smooth curves. In this test, as in the torsion and tension tests, the curves approached a horizontal line in the neighborhood of 10,000,000 repetitions, and in all cases the value at 10,000,000 cycles was taken as the endurance limit.

Material—A large number of different steels was experimented with, ranging from ingot iron with 0.023 per cent carbon to high-carbon steel, nickel steel, nickel-chrome, and other alloy steels. Each was tested with various heat treatments: as received, annealed, water-quenched and drawn at different temperatures, oil-quenched and drawn at different temperatures. The critical part of the specimen in each case was polished after turning to size, and different kinds of polish were tried out, without showing any significant differences whatever.

The differences in composition of the steels and their differences of treatment produced a total range of 47,000 to 201,000 in tensile strength, 30,000 to 165,000 in yield point, and 40,000 to 124,000 in ultimate torsional strength.

Reversed-Bending Endurance—Plotted on paper with logarithmic abscissas and arithmetic ordinates the results of the reversed-bending tests yielded fairly regular curves; Fig. 1 is a typical set of diagrams, in which, however, the curves have not been drawn. All the plots became practically horizontal beyond 10,000,000 cycles, so that only the horizontal portion was drawn. The series of diagrams in Fig. 1 indicates that the endurance limit is raised by quenching, and is raised more by water quenching than by oil quenching; that it is decreased by drawing about in proportion to the temperature; and that it is lowest for the annealed material. In this respect all the endurance tests gave the same indication.

In a number of experiments a specimen was first subjected to 10,000,000 or more cycles at a stress below its expected endurance limit, then another 10,000,000 cycles at a stress slightly higher, and so on in 1,000 or 2,000-lb. steps until the specimen broke. Each time the stress was raised, counting of cycles started at zero for the purpose of entering the result in the diagram. It was found that a marked increase in endurance resulted from the low-stress repetitions.

Tests made on material from crank shafts of battleships, submarines and airplanes showed lower endurance limits

FIG. 1—REVERSED-BENDING ENDURANCE CURVES
For steel of 0.24 carbon and 0.45 manganese. Horizontal dash lines represent the point where the curve of the results intersects the 10,000,000-cycle vertical, which is taken as the endurance limit.

values differ; and (2) repeated stressing at a stress which does not produce fracture tends to strengthen the piece, giving it a higher endurance than possessed by a similar piece without such preliminary stressing. The effect of

for specimens taken in the transverse direction or from the block cut out between the crank webs, where the material had not been forged as thoroughly as elsewhere.

Reversed-Torsion Endurance.—In torsion the results were closely parallel to those in tension, both as to the effect of heat treatment and as to the merging of the failure curve into a horizontal line at about 10,000,000 cycles. The effects

of "fiber" as indicated by the results on transverse specimens from shafts also corresponded to those obtained in bending.

Impact Endurance.—For the principal impact endurance tests, a specimen of $\frac{1}{2}$ -in. diameter was used, with a parallel-sided notch at mid-length of 0.4-in. bottom diameter and bottom radius $\frac{1}{16}$ in. Other tests, made with a V-notch

FIG. 3—REPEATED-IMPACT ENDURANCE CURVES

The left-hand ordinate of each curve is the energy required to break the specimen in one blow. The tests with smaller amounts of energy per blow extend to values requiring more than 20,000,000 blows for fracture and include one test with more than 40,000,000 blows in which fracture did not result.

specimen of much sharper curvature at the bottom of the notch, confirmed the results.

A typical series of curves is shown in Fig. 3. The curves are remarkably smooth. The ordinates at the left ends of the curves, representing single-blow impact fracture, are roughly proportional to the Charpy impact values, though differing from the latter because of the difference in form of specimen. The endurance limits (ordinates of the horizontal portion at the right) have no relation to the Charpy values, however, but are proportional to the reversed-bending endurance limit. For the seven materials represented in Fig. 3 the ratio of the reversed-bending endurance (lb. per sq. in.) to the impact endurance (energy per blow) ranges from 550,000 to 670,000, and four of the ratios lie between 610,000 and 630,000. The Charpy values for these materials, on the other hand, range from 3.7 to 29.1. Thus, impact endurance does not depend on the Charpy value but depends directly on the reversed-bending endurance limit.

If an attempt is made to measure impact endurance by a relatively small number of blows, so that the value found would lie in the sloping part of the curve in Fig. 3, the result would be influenced jointly by the Charpy value (which controls the position of the curve at the extreme left) and the bending endurance (which controls the limit at the right), and therefore would not measure any single property of the material nor indicate the true impact endurance.

Endurance Ratios—A tabulation of endurance limits and their ratios to each other and to static strength properties is given in the table. The endurance ratio, or the ratio of reversed-bending endurance limit to tensile strength, is given in column 10. For the different steels the average ratio varies from 0.355 to 0.503. The chemical composition appears to affect the endurance ratio. For high-carbon steel the average ratio is about 0.35, while for low and medium-carbon steels it is about 0.41 and for 3½ per cent nickel steel it is about 0.50.

Fuller study of the endurance ratio is represented by the diagrams Fig. 4, where endurance limit is plotted as ordinate and tensile strength as abscissa, separately for different kinds of steel. The straight lines are drawn so as to pass through the origin of co-ordinates, and their tangents represent the endurance ratios. In the lower

diagram the lines from left to right represent respectively ingot iron, mild steel, and high-carbon steel; the endurance ratio is least for the latter. In (b) of Fig. 4 the two lines represent nickel steels and medium-carbon steels, the former having the higher ratio. Diagram (c) represents annealed carbon and alloy steels. Ingot iron is at the left of the mean line drawn, high-carbon steels are at the right or below, and nickel steels form a group of seven points well above the line. The diagram is taken to indicate that in the annealed condition the endurance ratio of 3½ per cent nickel steel is higher than that of chrome-molybdenum, chrome-vanadium, low nickel-chrome steel, and all carbon steels except ingot iron. The endurance ratio for annealed high nickel-chrome steel has not yet been determined.

Fig. 5 gives the torsional endurance ratio, referred to tensile strength and torsional strength respectively. In both cases the plotted points fairly well fit straight lines passing through the origin, just as in the case of the reversed-bending ratio. Fig. 5 also indicates that the endurance ratio of nickel steels is higher than that of carbon steels (0.28 as compared with 0.22). The crank-shaft diagram in Fig. 5 represents a ratio of 0.22, as for carbon steel bar material.

It appears that the endurance ratio decreases as the percentage of pearlite in the steel increases. Even the endurance limit itself is lowered by the first addition of cementite to ferrite; with greater increase of carbon and therefore of cementite the endurance limit is increased, but the ratio drops. Addition of nickel apparently strengthens the ferrite, with the result that the endurance ratio is raised.

Studies of the ratios of endurance limits to proportional limits do not show as regular relationship as the ratios to ultimate strength. The plotted lines generally start from the origin with a slope of about 45 deg., and then gradually curve to the right, concave downward. Thus for low

FIG. 4—ENDURANCE RATIOS FOR VARIOUS STEELS
Relation between tension-compression endurance limit and tensile strength. The plotted points show a fair straight-line relationship. Lines drawn to pass through the origin.

FIG. 5.—TORSION ENDURANCE RATIOS

Upper diagrams show relation between torsion endurance limit and tensile strength. Lower diagram shows relation to torsional strength. The crank-shaft diagram represents a ratio of 0.25, as for carbon steel bar material.

or moderate proportional limit, the endurance limit is about equal to the proportional limit, while for high proportional limit the endurance limit is only about half. The ratio of endurance limit to proportional limit is conspicuously lower in low and medium carbon steels than in nickel steels of the same strength.

That endurance is not related to brittleness, or in other words to the property which causes failure of a notched specimen under impact, is shown by comparison of the reversed-bending and torsion endurance limits with the Charpy values, and also by the fact that the impact endurance limits depend only on the former. The impact endurance tests were made on notched bars, and here high-carbon steel having a Charpy value of only 2.9 proved superior in endurance to similar bars of low-carbon steel having a Charpy value of 23.6. It is concluded that, whether or not a machinery part contains abrupt change of section, its fatigue-resisting quality is independent of the impact value of the metal, provided the energy of impact is not so great as to cause fracture after less than about 1,000,000 blows.

Endurance Range.—Some special experiments to supplement those already referred to were made to investigate the magnitude of the endurance range in various positions within the elastic range. With steels heat-treated so as to have proportional limit nearly twice their endurance limit, it was possible to vary considerably the position of the endurance range within the elastic range. From the results it is concluded that the variation of the endurance range within the elastic range is slight. Even when the stress oscillates between zero and a positive value, the endurance range is apparently not more than about 10 per cent less than when the stress oscillates between equal positive and negative values. It is further concluded that *within the elastic range the endurance range may be assumed to be practically twice the endurance limit.*

Mechanical Agitation of Scum in Vent Chamber of Imhoff Tanks

CONTINUOUS agitation of the scum forming in the vent chambers of the Imhoff tanks treating the sewage at Newton, Kan., prevents "boiling over," the bugaboo of so many operators of sewage plants. W. C. Conrad, mayor of Newton (not an engineer) and Mr. Bachus, a local machinist, have devised a motor-driven walking-beam arrangement carrying four mill-conveyor screws upright in the vent chamber. A. P. Learned, of Black & Veatch, consulting engineers, who designed the plant (see *Engineering News-Record*, Feb. 10, 1921, p. 249) states that such satisfactory operation was secured that a similar arrangement has been installed in the plant at Enid, Oklahoma.

The Newton plant consists of a pumping station, Imhoff tank, sprinkling filters, final settling tank and sludge drying beds. Because of the strong sewage, with the consequent large amount of gas generated in its digestion, and the fact that the walls of the vent chamber

WALKING BEAM DEVICE FOR AGITATING SCUM IN GAS VENT OF IMHOFF TANK

The pipe frames supporting the four screws are counter-weighted and fastened to the walking beam at one point so that each screw has the same travel. Operation was unsatisfactory when the travel was unequal.

are only 1 ft. above the level of the outlet weir, the tank often boiled over. The mayor's idea in agitating the scum was to give a free passage of gas and to prevent its hardening, which entrained the gas.

The walking beam, of 1-in. angles, well laced and braced, is mounted over the center of the vent chamber parallel to the long dimension. Fastened to each end of the beam is a frame of 2-in. pipes mounted at one point and held by a spring so that each frame rides at the same angle as the walking beam is raised and lowered. To the bottom of each frame are attached mill screws 8 in. in diameter and 4 ft. long. To one end of the walking beam is attached a lever actuated by a large pulley belted to a smaller pulley run in turn by a shaft driven by a worm gearing mounting on a motor driving one of the sewage pumps. The gear and pulley arrangement reduces the speed of the motor so that the walking beam operates at four to five cycles per minute and the travel of the screws up and down is 12 to 18 in.

Why Steel Forms Were Successful on One Concrete Job

Construction Typical of Many Others Showed That Use of Steel Forms for Concrete Floors and Columns Made for Speed, Economy and Neat Appearance

BY RAYMOND C. REESE

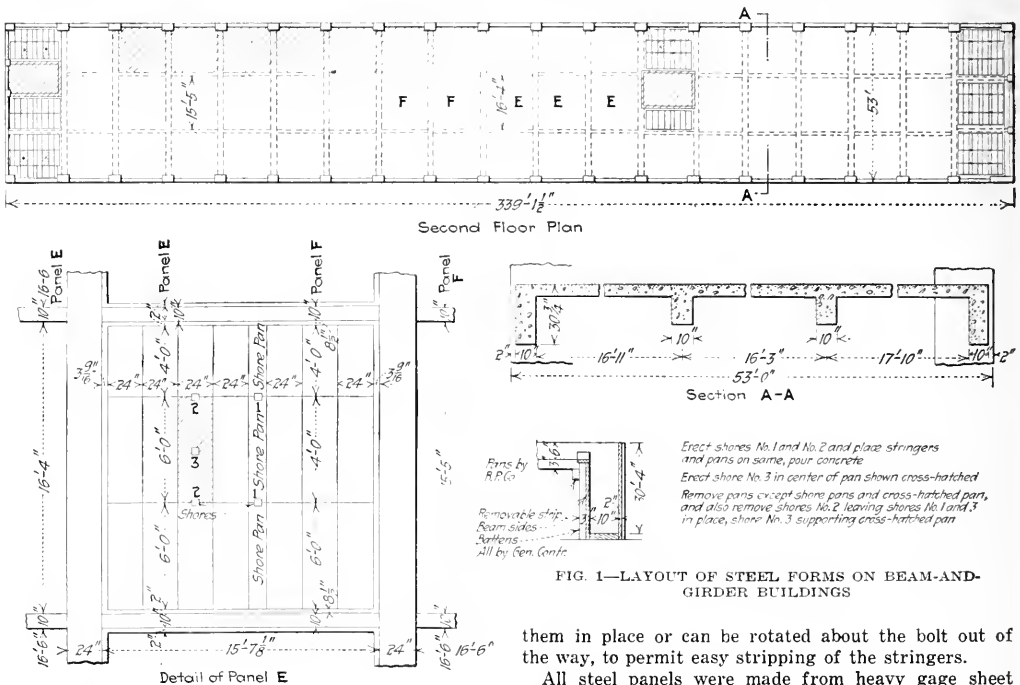

Chief Engineer, Building Products Co., Toledo, Ohio

IN THE construction of a new group of reinforced-concrete buildings for the Hupp Motor Co., at Detroit, Mich., steel forms were used so successfully for the floors and columns that the experience there seems to be of especial value to those who wish more light on the availability of this type of formwork.

The group consists of two four-story parallel buildings of the flat-slab type, each 73 ft. 6½ in. wide by 396 ft. 9 in. long, numbered 9 and 10, respectively, and a third building, No. 11, in which beam-and-girder construction was considered preferable to flat slab be-

preparations were made in advance to insure an average daily progress that would complete the work in the scheduled time. The layout required for Building 11 is shown in Fig. 1.

Fig. 2 shows a typical panel. Shores of 4x4's were set up at proper intervals (averaging one to every 30 sq.ft. of floor) with 2x8-in. stringers resting upon shoulder blocks, fastened to the shores. Wedges were interposed to allow for leveling up. The arrangement of buttons is particularly worthy of note. These can be turned up on the outside of the stringers to hold

cause of the machine loads and spacing. This latter building is 53 ft. wide by 339 ft. 1½ in. long, four stories high. The first story is 24 ft. 6 in. high plus a 4-ft. track depression, which necessitated very long shores. Even with beam-and-girder construction it was found both feasible and economical to use the same forms for the solid slabs between the beams—a rather unusual arrangement but since repeated on other work.

The decision of the general contractors to sublet the formwork to steel form erectors was made on a competitive price basis, as compared with wood centering. There was a saving of about 10 per cent in favor of the steel forms. One of the first steps was to make complete working details showing the arrangement of steel panels, location of shores, run of stringers, detail of forms for drop heads, etc., which means that all

them in place or can be rotated about the bolt out of the way, to permit easy stripping of the stringers.

All steel panels were made from heavy gage sheet steel to prevent distortion. They were provided in widths of 1, 1½ and 2 ft., and in lengths of 4 and 6 ft., thus making only a few sizes to stock and handle, and likewise proving very feasible and adaptable in actual practice. These panels conformed to the floor layout within a few inches, and variations were filled in with a strip of wood. The 1-ft. steel panel had open ends so that shores could extend up into the panels and remain there for permanent shoring as shown in Fig. 3. The other steel panels were made with solid ends and all of the steel panels or forms were manufactured with stiffening ribs arranged at short intervals. Two or three days of good weather allowed the stringers and intermediate steel panels to be stripped and used on the next set-up leaving shores and permanent shore panels to support the floor until the deck above was poured.

FIG. 2—CLOSE-UP OF UNDERSIDE OF STEEL FLOOR FORMS ASSEMBLED

Progress of Work—The storage site where the material was to be stored was not particularly convenient being some little distance from the site of the buildings and separated by a railroad track over which a large amount of switching took place with consequent delay to the trucks. This was an unavoidable handicap but did not interfere with the completion of the work within a specified time.

The contractor first placed the concrete floor on the ground, thereby affording a firm foundation upon which to start shoring. The first operation was to build drop panels of wood to form plinths above the column caps. The columns were circular, spirally hooped, with a flaring cap and were formed with steel column molds. Experience has proved that the only way to obtain proper alignment and to reduce erection cost is to put up the drop panels in the form of strongly braced towers which are aligned in both directions and wedged up to grade. After these are firmly braced in position they establish reference points between which the steel panels are placed. Fig. 5 shows very clearly the arrangement of these towers.

On Sept. 11, 1922, the first steel forms or panels were placed for Building 9, shown by Fig. 4, and the erection schedule calling for completion of the concrete work by Nov. 11 necessitated strict adherence to the established routine. The steel form area shown in Fig. 4 is the result of part of the first day of form placing. Fig. 5, taken two weeks later, gives a good conception of the entire layout and shows the tower for the second floor of Building 9 practically completed. It also shows towers being started on the second floor and part of the first floor on Building 10, while on Building 11 the first floor is entirely completed. This represents only two weeks progress after the first forms were placed.

Two weeks later the third floors of Buildings 9 and 10 were started and the second floor of Building 11 was about finished. This progress schedule was carried forward steadily throughout the entire job.

On Nov. 11 the last concrete was placed. The chart which was prepared by the contractors for their progress schedule on Sept. 11 called for approximately 240 yd. per pouring day and made no allowance for mishaps or other contingencies. The usual difficulties were encountered, such as delay in the delivery of cement (the railroads being fearfully tangled up at that time), loss and replacements of labor, delay in pouring owing to trouble with cement plant and delays in trucking the material from the storage site; notwithstanding these handicaps the work was completed on the exact date predicted.

This job typifies co-operation between the contractor and the subcontractor as it involved a fairly good sized area of buildings and was carried through by all parties to their mutual satisfaction, and it will serve better as a typical illustration of steel formwork than one on which unusually favorable conditions enabled extremely low costs and unusually rapid programs to be attained.

The subcontractor's form-setting crew for both steel pans and column work, including handling of all slab shoring, fabrication and handling of drops, consisted of 20 men and a superintendent. This crew carried the job through to completion and formed 300,000 sq.ft. of floor in 60 calendar days. The attainment of such speed as shown in this particular instance is not an extraordinary accomplishment in the writer's experience. The explanation of maintenance of the speed schedule is based upon the fact that steel forms make possible the use of considerably less shores than are used with most forms; and the most important fact, that the steel form crew was trained man by man to perform certain special operations, each with the utmost speed. Because one man or set of men have just one thing to do they become expert and attain the highest possible speed in the performance of their special function. By this it is possible to obtain the highest speed from labor employed over the job and to use less men on a job of this character than would be necessary with other systems of forming.

FIG. 3—PERMANENT SHORING AND SHORE PANELS IN PLACE

One of the points encountered on all industrial buildings is the placing of inserts for fastening shaft hangers, sprinkler pipes, etc. When wood forms are used, these are screwed or nailed down. Metal forms have made possible the use of mastic cement which fastens the insert firmly to the metal forms. A large number of inserts were used on the Hupp job and by the use of this cement it was possible to place inserts at a cost of 1¢ each.

Construction Precautions—Great care was taken to see that materials were delivered to proper points and neatly piled ready for use. As soon as forms were stripped they were moved to the side wall of the building ready to be carried to the next point, loaded on buggies which were elevated by a boom on the tower. If this movement of forms had been only from floor to floor it would have simplified movement considerably and greatly reduced the handling charges, but as it was,

a whole lies in the small amount of lumber required. It is generally accepted that forms for a flat-slab job made up entirely of lumber require from 3 to 3½ ft.-b.m. per square foot of contact area, while with the system of steel forms used on this job, the requirements averaged ¼ ft.-b.m. On small jobs, where the number of re-uses is limited, a little more will be required, while on very large jobs it is possible to use a little less.

Furthermore, none of the lumber used in the steel form system comes into contact with the concrete and is consequently in good condition and has a very high salvage value. In fact it can be used indefinitely from job to job merely at the expense of freight and handling. On the Hupp Motor Group, the lumber was furnished by the general contractor who had already placed partial orders for material required, but was fabricated by the subcontractor.

The partial layouts, Fig. 1, show how nearly the

FIG. 4—SET-UP OF PANS ON STRUTS AT BEGINNING OF CONSTRUCTION

the forms were moved in turn from building to building as progress required.

Emphasis has been made of the point of centering towers to line and grade and having them securely braced. A first glance would see a possible economy in the formation of less substantial towers, but experience has proved that the care and attention given to the construction of well braced towers, accurately lined, is a worth-while ultimate economy. Another point of economy consists in running long lines of shores at one time. It is expensive to spot a few shores here and there, but when a reasonable run can be pushed through at one time, the unit costs are cut considerably. The making of shores can be studied and systematized just as carefully as production work in a large factory. This is especially important when it is considered that a nominal amount of shores run well into the thousands in quantity. Adequate ribbon bracing of all shores is also important in the obtaining of a neatly finished job. It takes but little longer to do this and in the end it pays for itself.

One of the big economies of the steel form system as

forms covered the area to be formed and how little filling in was required. They give a good idea of the adaptability of the system. It has proved much more successful in actual practice than one would expect from a cursory examination. The chief matter of adjustment is obtained by using "pads" or fillers on the drop heads to take up the play between the actual drop as designed and the opening left by the panels. At these points practically all the slack is taken up. At spandrel beams it is well to follow the details indicated, leaving a few inches of filling in between the actual beam side and the first panel, both to facilitate the stripping of the forms and to give another point at which to take up play. This detail has practically become standardized.

Conclusions—The following conclusions are the result of the writer's experience with the system:

(1) On buildings of such size that a sufficient area for one set-up is obtained with an area of forms that will permit of four or more re-uses, steel forms can be used more economically than wood forms, and as the number of re-uses increases, the economy increases.

(2) But little filling in between forms and spandrel beams or drop panels is required.

(3) No difficulty has been experienced due to the combination of steel forms with wood beam and drop panel forms. A little forethought in the design of the wood forms is all that is required.

(4) Inserts are readily and securely held by mastic cement and can be placed at a minimum expense.

(5) Steel forms produce a ceiling that is much smoother than can be obtained with the use of ordinary wood forms.

Whether or not steel forms are applicable to the par-

progress schedule, with the use of very few men, has enabled us to disregard the labor situation to some extent, as we carry a regular force which can be kept busy at all times.

(4) Quality and Finish of Work Required. This particular item is one which is the subject of a great deal of discussion. On this particular job we were obliged to furnish a high class of finish on the concrete, which in our opinion would have been impossible with other methods of forming.

The general contract for the Hupp Motor Group was let to the Everett Winters Co., of Detroit, Mich. The

FIG. 5.—PROGRESS ON HUPP GROUP AFTER TWO WEEKS OF FORM LAYING
Note towers supporting the column head panels

ticular construction is a question involving the calculation of forming cost on the particular job, considering especially the following headings:

(1) Number of Re-Uses to Which Forms Can Be Put on a Particular Job. This involves, among other items, the area of forms required in one set-up. Usually not less than 5,000 to 10,000 sq.ft. is desired at a time, and sometimes even more, depending upon the capacity of the concreting plant.

(2) Cost of Lumber. This is a highly influential factor in determining whether a job is one for steel forms or not, as steel forms require from 50 to 60 per cent less lumber than other methods of forming. Where lumber is high, the ultimate economy in the use of steel forms is easy to perceive. Steel forms can be used economically on a much smaller floor area where lumber is high than is possible where lumber is appreciably cheaper.

(3) Scarcity of Labor. The fact that we have been able to form large jobs and keep up with a definite

subcontractor for formwork was the Building Products Co., of Toledo, Ohio. The Blaw-Knox slab forms were used.

Mississippi Bridge at St. Paul

An engineering report is soon to be made on the proposed bridge over the Mississippi River at the new Ford plant, connecting the cities of St. Paul and Minneapolis. A commission to consist of at least five members was authorized by the last legislature, and the commissioner of highways was appointed chairman. The other members of the commission include the president of the council of each city and the city engineer of each city. This commission delegated the work of preliminary surveys and report to the two city engineers, N. W. Elsberg (Minneapolis) and George M. Shepard (St. Paul). Surveys have been made and a report will soon be made to the commission. The law provides for the issuance of \$800,000 in bonds by each city to defray the cost of the bridge.

Bridge Plaza Plans Successfully Presented by Aid of Model

Complicated Layout Made Clear by Use of a Model—Mechanical Arrangement to Show Traffic Movements

THE USEFULNESS of a model in presenting proposed development schemes to the public is well demonstrated in the case of the proposed Hudson County Bridge Plaza at Summit Ave. in Jersey City, N. J. The Hudson County Boulevard is the one north and south thoroughfare on the west shore of the Hudson River opposite New York City. It is one of the most important thoroughfares of the Metropolitan District, used as the Lincoln Highway carrying all the traffic south and west from New York City. Its importance will be greatly increased when the vehicular tunnel now under construction under the North River between Jersey City and New York is opened.

The alignment of the boulevard is fairly straight until it reaches the point, in the vicinity of Summit Ave., where it is carried over a depression, in which the tracks of the Pennsylvania and Hudson & Manhattan railroads are located, on a three-span structural steel deck bridge 342 ft. long and 60 ft. wide carrying a 40-ft. roadway and two 10-ft. sidewalks. The height

the cars do not come out onto the boulevard. All the bus lines with the exception of the Central Ave. line terminate near the south abutment of the bridge discharging and loading passengers on the bridge and around the curve immediately adjacent thereto. This is for the convenience of passengers in reaching the 15-ft. passageway which is the only avenue of access from the boulevard to the station. The buses from the north discharge passengers on the bridge and turn around in the two narrow streets forming Journal Square. The Bergen Ave. line uses these streets also but turns at the street intersection north of the bridge which is also the turn-around for buses from the south on the boulevard.

The two principal bus lines north and south on the boulevard carry monthly approximately 1,600,000 pas-

MODEL OF THE HUDSON COUNTY BRIDGE PLAZA

of the roadway over the tracks is 50 ft. The improved roadway beyond the bridge is 60 ft. in width. The existing bridge was built in 1894 when the boulevard was no more than a bridle path. Due to heavy traffic there is an excessive vibration throughout the entire structure, making necessary an immediate reconstruction.

In a northerly direction from the bridge the roadway curves to the left from the abutment through 51 deg. Likewise, going south, it begins to curve to the right immediately as it leaves the south abutment through 77 deg., then follows one full city block of tangent and another turn left through 45 deg., thus forming in all a very tortuous alignment. In this elbow curve is the center of great traffic activity which is due, in large measure, to the movement of passengers to and from the Summit Ave. station of the Hudson & Manhattan "Tubes," which is located just east of the south end of the bridge. In 1922 this station handled 24,000,000 passengers. This figure gives a fair indication of the magnitude of traffic in this section.

The great bulk of this passenger traffic is handled to and from the station by buses, private cars and taxis along the boulevard. The surface car traffic from Bergen Ave. does not directly affect the situation as

METHOD OF MOUNTING THE MOVING PARTS

sengers. To complicate the situation there is the through and local travel on the boulevard. The maximum eight-hour count of vehicles over the bridge including the buses is 15,000. These factors, the tortuous alignment of the boulevard, the narrowness of the bridge roadway, the inaccessibility of the station and the enormous growth of travel have caused a traffic congestion comparable in importance and magnitude to the larger traffic problems of the Metropolitan District.

The Proposed Rearrangement—In correcting the alignment of the boulevard by projecting a new street forming the hypotenuse of a triangle to divert part of the traffic from the principal turn of the boulevard where the traffic jam occurs, all the traffic difficulties of the section are corrected and essential facilities are readily evolved. The new street continues across the railroad cut and intersects the present roadway just beyond the northerly abutment. The two roadways over the tracks form the sides of an A-shaped bridge plaza 200 ft. in width at the northerly abutment or apex, 525 ft. in width at the base, the length or altitude being 465 ft.

Traffic Movements—This "A" shape made possible a one-way movement in traffic control. Within this space three large platforms are placed to separate the traffic south-bound on the westerly leg and north-bound on the easterly leg or roadway of the bridge. The two platforms parallel with the roadways form a center plaza wherein the north-bound vehicles or buses can be drawn away from the through traffic. Passengers are to be unloaded on the one platform and loaded from the other, the vehicles turning within the area. The large platform forming the cross-bar of the "A" is used as a receiving and unloading platform for south-bound passengers. The buses are operated along the lower or curved side of the platform. The upper or straight edge of the platform will be used for private vehicles from the north turning with the general traffic movement. The sides of this big platform can be used for unloading passengers from vehicles continuing north

and south beyond the plaza. There is parking space in the center between platforms and along the side of the platforms for taxicabs and momentary stops of private vehicles. Private vehicles can also park along the roadway sides of the platforms.

Stairways lead from the three island platforms to two longitudinal and one main or transverse passageway built directly underneath the bridge floor. The transverse passageway is in line with the existing passageway to the station and will be built underneath it to the width of 20 ft. Other stairways from the various corners of the plaza connect with these passageways to make it possible to reach the station or the three island platforms from any point on the surface without crossing the roadways. Hudson County and Jersey City authorities jointly will remove the buildings in Journal Square, thus giving Bergen Ave. proper access to the boulevard.

Plaza Model—After the preliminary plan had been approved by the Board of Chosen Freeholders it was found that there was considerable misinterpretation and misunderstanding of the workability of the plan. To correct these false impressions a mechanical model was made so that the entire project would be visualized. The model was made to scale of 1 in. equal to 20 ft., the scale of the plan of the general layout. From this plan the buildings, roadways, piers, etc., were readily superimposed on a large piece of heavy cardboard on which were drawn also the lanes of all lines of traffic and the plan of the mechanical effects. The roadway of the model is made of laminated wood about $\frac{3}{8}$ in. in thickness. Slots were cut in the roadway in the center along the principal lines of traffic movement making loops of each separate route. Under the ends of the roadways were stepped sprocket wheels or cone pulleys so set that the face of each step came directly under the turn in the corresponding slot in the street. At the minor changes in direction stepped fixed guides were used instead of sprocket wheels. The main sprocket was geared to a crankshaft extending outside the frame of the model. When the wheels and guides were in place chains were fitted to them, one chain under each slot in the street surface. When the chains were adjusted hairpins were secured to each chain at intervals along its length by sticking the ends of the hairpins through the links of the chain. These pins were cut off about $\frac{1}{2}$ in. above the street surface and a tiny pressed pewter automobile was secured to the ends of each pin by sticking them in hot sealing wax poured into the body of the car. The automobiles on each line were colored differently to distinguish the separate traffic routes. Other automobiles were secured directly to the street surface showing position of parked cars.

When the whole model was assembled it was possible, by turning a propelling crank, to cause all the lines of automobiles, buses etc., to move around the plaza along their proper routes showing continuous movement without interference.

The buildings were made of cardboard with the architectural features drawn in elevation. Only the most important buildings of the section and those buildings necessary to show the relative position of the new street and the bridge plaza were made a part of the model.

The improvement is being carried on by the Board of Chosen Freeholders through the office of County

Engineer Frank J. Radigan. The plans were prepared and the model was made in the office of A. Burton Cohen, consulting engineer, New York City, assistant engineers, Robert L.H. Tate and Harry K. Wilson.

Why Sacramento Garbage Collection Bills Are Presented by Agents

IN COLLECTING from the householders of Sacramento, Calif., the monthly charge which the city makes for removing garbage, the bills are presented at the door by employees of the city. Three collectors have been found adequate, with occasional aid from the head of the department, to collect the monthly bills for the entire 15,000 premises which subscribe for the garbage removal service. Owing to multiple payments at real estate offices, etc., only about 12,000 addresses have to be visited each month by collectors. Solicitation in person is made rather than mailing the bills because the additional cost is more than offset by the lower percentage of bad bills. Another advantage of personal solicitation is that the collector can report attempts to evade proper classification, failure to observe sanitary regulations, etc.

With a minimum charge of 50c. per month for weekly removal from one 20-gal. garbage can, the average collection per address is slightly over \$1 and the total collection \$12,500 per month from the 12,000 addresses.

Collectors carry a carbon copy attached to each bill. At addresses where no one is found at home the collector uses a rubber stamp to mark the bill "Pease remit by check with bill attached, or bring to City Hall before the first of the month." After repeated failures to make collections the collector leaves a bill marked "If this bill is not paid within three days service will be discontinued." Under this system only a fraction of 1 per cent of the bills go unpaid.

Forests Prevent Silting of Reservoirs

Abstract of paper on Soil Erosion and Forest Cover in Relation to Utilization of Water Power, with Special Reference to the Southeast, presented by W. W. Ashe, Assistant District Forester, U. S. Forest Service, before the Southern Appalachian Water Power Conference.

IF THE ENORMOUS resources of our rivers are to be adequately developed it must be through a series of storage reservoirs such as have been tentatively located on the upper regions of some streams. As the value of such reservoirs depends largely upon their life and the maintenance of their storage capacity, erosion of soil is the all-important factor in determining the number of years which will elapse before the fertile soil and earth removed by heavy rains from the land in their catchment areas will fill them, gradually in most cases, but surely if any erosion takes place. Erosion is not a natural condition for such streams as lie above 1,500 ft. altitude, and in many cases it is entirely due to the removal of the protective cover of the forest with its litter and humus.

Hydrographers claim that forests have little effect on stream flow, but this is to be questioned except in the regions of sandy soil where the forest influences are usually at a minimum. These influences rise to a maximum in the Sierras of California, in the southern Appalachians, and in the southern Piedmont, where erosion is an important factor. Nor does grass cover take the place of forest cover, because grass cannot be adequately maintained without periods of cultivation and consequent erosion, and moreover a grass cover lacks the permeability of forest cover with its deep root zones and channels resulting from the decay of roots.

Endurance of Steel—Second Illinois Report

Correlation of Endurance and Heating—Tests on Combined Tension and Bending—Goodman's Law Not Verified

A DEFINITE endurance limit for wrought steels was established in the early series of tests carried on at the University of Illinois as a co-operative research between the Engineering Experiment Station of the University, the National Research Council, Engineering Foundation, and the General Electric Co., as reported in the Illinois Bulletin 124, published two years ago. Extensive additional tests have just been reported on in Bulletin 136 of the station, by H. F. Moore and T. M. Jasper. These additional tests con-

Endurance limit decreases with increase of drawing temperature from 600 to 1,400 deg. F.

firm all the results indicated in the prior report, and in addition deal at considerable length with repeated stresses of combined tension and bending, in which case the stress in the outer fiber of the metal varies from a high tension to a low compression or from a high tension to a low tension, instead of varying between equal tension and compression values as in the previous reversed-bending tests. The results indicate that the so-called dynamic law of Goodman does not hold, but that higher endurance values are obtained than would follow from this hypothesis.

In the recent work carbon steels ranging from 0.02 to 1.20 carbon, and two chrome nickel steels with about 3½ per cent nickel, were tested. Reversed-bending tests were carried out on a specimen supported at both ends and loaded in the middle, while rotated at a speed ordinarily 1,500 r.p.m. Substantially no effect on the results was found by changing the speed to as low as 200 r.p.m. or as high as 5,000 r.p.m. The torsion tests were made in machines of two different types. In all cases the specimens were cut from the material longitudinally (in the direction of rolling).

Endurance Limit Confirmed—The conclusion from the earlier tests that wrought ferrous metals have a definite endurance limit—a stress below which the material will stand an indefinitely large number of reversals—is confirmed by the more recent tests. All the plots such as those of Fig. 1 (reversed bending)

FIG. 2—REVERSED-TORSION CURVES

and Fig. 2 (reversed torsion) show a sloping part changing sharply to a horizontal part (in plottings on double logarithmic paper). Special search was made to discover whether the horizontal part of the curve shows a tendency to drop at very high values of reversals, and a number of tests were run to about one billion reversals at values just below the endurance limit deduced from a smaller number of reversals. No evidence of a lowered endurance limit at this very high number of reversals was found.

Heating Limit Identical With Endurance Limit—Complete confirmation was obtained of the previously
